8 (1) Every person who shall contravene any such regulation as aforesaid, or shall knowingly carry out or procure or take part in the burning of any human remains except in accordance with such regulations and the provisions of this Act, shall (in addition to any liability or penalty which he may otherwise incur) be liable on summary conviction to a penalty not exceeding £50 Provided that any person aggrieved by any conviction may appeal therefrom to quarter sessions (2) Every person who shall wilfully make any false declaration or representation or sign or utter any false certificate, with a view to procuring the burning of any human remains shall (in addition to any penalty or liability which he may otherwise incur) be liable to imprisonment with or without hard labour not exceeding two years (3) Every person who with intent to conceal the commission or impede the prosecution of any offence procures or attempts to procure the cremation of any body or with such intent makes any declaration or gives any certificate under this Act, shall be liable to conviction on indictment to penal servitude for a term not exceeding five years

9 The burial authority may demand payment of any such charges or fees for the burning of human remains in any crematorium provided by them as may be authorised by any table approved by the Local Government Board and such charges or fees and any other expenses properly incurred in or in connexion with the cremation of a deceased person shall be deemed to be part of the funeral expenses of the deceased

10 Nothing in this Act shall interfere with the jurisdiction of any coroner under the Coroners Act 1887, or any Act amending the same and nothing in this Act shall authorise the burial authority or any person to create or permit a nuisance

11 The incumbent of any ecclesiastical parish shall not, with respect to his parishioners or persons dying in his parish be under any obligation to perform a funeral service before at, or after the cremation of their remains, within the ground of a burial authority but, upon his refusal so to do any clerk in Holy Orders of the Established Church not being prohibited under ecclesiastical censure may with the permission of the bishop and at the request of the executor of the deceased person or of the burial authority, or other person having charge of the cremation or interment of the cremated remains, perform such service within such ground

12. In any table of fees respecting burials to be made or approved by the Secretary of State a fee may be fixed in respect of a burial service before at or after cremation and if no fee is fixed the fee if any, fixed in respect of a burial service shall apply

13 Sections 52 and 57 of the Cemeteries Clauses Act, 1847, and any similar provisions in any local and personal Act authorising the making of a cemetery, shall apply to the disposition or interment of the ashes of a cremated body as if it were the burial of a body

14 As from the date at which regulations under this Act come into force any provisions of any local and personal Act for the like purpose as this Act and any by laws or regulations made thereunder, shall, so far as they relate to that purpose cease to be in operation

15 This Act shall come into operation on the first day of April one thousand nine hundred and three

16 This Act shall not apply to Ireland

PROSECUTION UNDER THE PUBLIC HEALTH ACT—At the Moot Hall police court, Newcastle, on August 30th, a young man, resident at Benwell, was charged with being in a public street whilst desquamating after scarlet fever The defendant said that he had to work in order to maintain himself and there was no hospital for him to go to One of the officials said that the Benwell and Fenham council had made no provision for cases of that kind Sir Riley Lord said that the bench would fine defendant 2*s* 6*d* and 1*s* 6*d* costs He added that they hoped that the council would make some adequate provision for cases of that sort. The bench thought that the council was quite as much to blame as was the defendant.

THE ANNUAL PATHOLOGICAL MUSEUM OF THE BRITISH MEDICAL ASSOCIATION

WHEN the Annual Museum of the British Medical Association was originated, the idea of the founders was that it would form a valuable means of education and interest to the whole profession, and particularly to those who were engaged in busy country and provincial practices, if all the different museums of the metropolis and the chief towns were to lend the additions which had been made to each museum during the preceding 12 months If this idea were still carried out it would, indeed, form one of the most interesting and instructive features of these annual gatherings. Unfortunately, the trade element crept in, for at first the mercantile exhibits were included in one Annual Museum. These soon became a most valuable source of income and at last the trade exhibits have become totally separated and the income derived from them, instead of being devoted to collecting and providing transit for interesting specimens and complex apparatus for exhibition in connexion with its quondam partner it is presumably expended in other direction. Last year at Cheltenham, the Pathological Museum was crowded into an extremely small room adjacent to the spacious winter garden in which the mercantile exhibits were spread out Both were, it is true, beneath the same roof and the visitors to both were numerous. This year at Manchester they were completely separated. Interesting as were the various exhibits in this year's museum it was only a few of the more enthusiastic workers in the profession who had energy sufficient to climb to the top of the Owens College and who succeeded in finding their way amid the labyrinth of turnings Those who did arrive at their destination were heard to express a hope that now at any rate they would see some of the latest and most scientific apparatus for pathological research, and that since Manchester was one of the greatest industrial centres of the world they would certainly see all that pathology could teach concerning diseases relating to the various industries

Arsenic has been a great deal in evidence lately and to it quite a number of diseases are now being attributed, such as peripheral neuritis, various skin lesions, and cancer even beri beri was mentioned at one of the discussions in the sections. One of the exhibits in the museum consisted of an unpretentious pint bottle labeled Manchester Snow Water about which many interesting things might be said. The snow was collected after a dense fog and the soot contained in the bottle was entirely derived from the snow water contained in the bottle. This water contained arsenic derived from the soot, in the proportion of one grain of arsenious acid in 108 gallons of water During the month of December 1900 Professor S. Delépine finding that coal and coke contained unexpectedly large amounts of arsenic tested for arsenic the soot contained in the flues of chimneys the dust in Manchester houses, and the dust deposited on the leaves of trees and shrubs, and found an appreciable amount of arsenic in each case No arsenic could be found on leaves collected in Switzerland or in the Lake District in England. He was therefore led to infer that large amounts of arsenic were constantly deposited from the air in Manchester and it was to test this point that the snow water was collected. The inhabitants of large towns where much coal is burnt must therefore inhale a very appreciable amount of arsenic, more especially during foggy weather The snow water evidently contained also a very large amount of organic impurities which might be seen as a thick sediment at the bottom of the bottle This gives some idea of the enormous amount of organic impurities which the inhabitants of big towns like Manchester and London must inhale and constitutes a grave cause for anxiety and for efficient action in the way of prevention. The fact that the snow water contained arsenic, which could also be found in the soot of chimneys is a very interesting fact to those who like Mr Jonathan Hutchinson hold that arsenic can produce cancer Chimney sweep's cancer has long been a puzzle to pathologists for it could not altogether be attributed to mechanical irritation Sir James Paget long ago described in his own lucid way the changes which occur in the skin of chimney sweeps and there seems very little doubt that the features which he described correspond with those we now know as keratosis due to the internal administration of arsenic

The effects upon the skin produced by the internal administration of arsenic formed one of the most interesting features of the exhibition. In a series of sketches exhibited by Mr Hutchinson (London) among the drawings selected from those added to the Polyclinic Museum during the past year No 217 showed the hands and elbows of a man in whom arsenical poisoning (discoloured skin pitted palms and psoriasis-like crusts on the elbows and knuckles) was induced by a short course of arsenic in full doses. Another of these exhibits represented the hands of a medical man living in New York who had been taking large doses of arsenic for a prolonged period of time and in whom arsenical keratosis appeared on the palms of the hands, and these subsequently became cancerous as shown in the sketch. Another plate showed the hands of a patient who had undergone amputation of a finger for epithelial cancer and in whom after the administration of arsenic numerous small warty growths (? malignant) had appeared in addition to the keratosis, on the hands and various parts of the body

An interesting portrait in the same series exhibited a girl of about 20 years of age who was the subject of that curious condition Hemiatrophy of the Face, resulting from "herpetiform morphœa. An important feature was the very advanced condition of atrophy of the right side of the tongue. This was probably the first instance in which unilateral atrophy of the tongue had been demonstrated in connexion with morphœa. Beside the preceding there was exhibited for comparison a case of unilateral atrophy of the tongue which had existed for some years after destruction of the lingual nerve by a sloughing abscess of the neck. The atrophy in this patient was much less than in the case of morphœa. Do not a study and comparison of these cases lead to the conclusion that the initial lesion in the morphœa of Erasmus Wilson in reality involves the nerve trunk supplying the part affected (the fifth or lingual, as the case may be) in early life? Cases of identically the same hemiatrophy facialis have been reported where injury to the head attended by evidence of damage to the cranial nerves has been followed by facial hemiatrophy [1]

Among the photographs deserving special note was a series exhibited by Dr D Chalmers Watson (Edinburgh) illustrating various diseases of human beings produced experimentally in the lower animals One series illustrating nervous diseases in animals was communicated to the pathological section of the Association.[2] Another series illustrated experimental gout produced in poultry fed on a diet strictly limited to red meat and water joint lesions being produced and in the opinion of the exhibitor these researches tended to emphasise the "individual factor" of disease.

The anatomy and pathology of the nasal cavities received a notable addition in the well-described series of 10 specimens and 34 plates exhibited by Mr F H. Westmacott (Manchester). But as an illustration of the patient analytical industry which is so marked a quality of German observers, it would be hard to find a better instance than the coloured pastel sketches which occupied the entire side of one large screen. A few of these depicted the development of the auricle in various mammals but the large majority of these pictures and many of the 556 smaller sketches in a book also exhibited, illustrated the appearance of the tympanic membrane in various stages extending over a course of years, of a rare condition which has been described as "blue ear-drum or tympanum ceruleum."[3] These were not described in the catalogue but in the course of conversation with the exhibitor Professor Rohrer (Zürich), we learned that they were all from one case in which the appearance presented was due to the formation of dilated and tortuous venules (varices) on the ear drum, derived from the jugular vein owing to a deficiency in the bony wall of the jugular fossa of congenital and possibly rachitic origin. The patient could hear perfectly well and presented no symptoms and the first question which spontaneously occurred to the mind was What was the practical use of so much labour But is not the practical utility of any subject generally found out late, when generations of patient thinkers and workers have spent their lives on it inspired only by the love of knowledge Many of the greatest discoveries in astronomy biology and pathology have been made by men who had not the remotest idea of their application at the time. Sooner or later, in the most unlikely studies the practical application comes, and comes as an unearned increment to knowledge pursued for its own sake

[3] Ueber die blaue Farbe des Trommelfelles—Tympanum coeruleum—und über das Auftreten von Varicen am Trommelfell, von Dr [illegible] Rohrer Zeitschrift für Ohrenheilkunde Band xxxi[illegible] Heft 1

Curiously enough another notable instance of this principle was to be found in the exhaustive series of specimens also relating to and illustrating the anatomy and pathology of the ear exhibited by Mr Arthur H. Cheatle (London) Dry bones for the most part, they exhibited the arrangement of the mastoid cells in different individuals and various other anatomical and pathological details of which the casual observer would find it hard to discover the bearing, since the catalogue gave no enlightenment, but to which the remarks we have just made again apply They formed a monument of patient industry Dr R. C Elsworth (Swansea), Mr Hugh E Jones (Liverpool), and Mr H Secker Walker (Leeds) also exhibited specimens in the domain of otology

If anyone were asked what was the prevailing feature of this exhibition the answer almost unhesitatingly would have been diseases of the osseous system Mr Noble Smith (London) exhibited an interesting series of 36 radiographs illustrating the pathological conditions appertaining to Congenital Displacement of the Hip-joints The points brought forward were that in a large number of cases the joints were malformed or rudimentary, the acetabula were deficient or practically absent and the heads of the femora were more or less indifferently developed. These defects varied considerably in degree and there were some instances in which the joints themselves, as shown by radiography, were quite normal with the exception of the displacement In a large number of cases the child had been born with a breech presentation and it was suggested that traumatic dislocation had in such instances occurred in consequence. Another point which these plates illustrated was the similarity in symptoms between congenital displacement and coxa vara, and it was considered by the exhibitor that an exact diagnosis could only be determined by a radiograph Dr J W Ballantyne (Edinburgh), Dr W Stoeltzner (Berlin), and Mr C E S Flemming (Bradford on Avon) exhibited an exhaustive series of Fœtal and Infantile Bone Diseases, including rickets, pseudo rachitic osteoporosis, chondrodystrophia fœtalis hypoplastica, phocomely, chondrodystrophia fœtalis hyperplastica, and achondroplasia The exhibit of Mr G A Wright (Manchester) bore also on bone diseases, and his series of 26 wet specimens of the various forms of Tuberculous Disease of the Hip joint repaid careful study A remarkably fine radiograph from a case under the care of Mr Edmund Owen (London) showed ossification of the tendo Achillis

An interesting series of 50 Vermiform Appendices removed from persons suffering from recurrent appendicitis, illustrating the various changes met with in the appendix in this affection, were exhibited by Mr F A Southam (Manchester) It would have given additional interest to this series if the nature of the originating concretions had been more particularly specified. In a few instances only this, was vaguely described as a "hard fæcal concretion," but at the present time observers ask how often this contains the bristle of a toothbrush, a cherry stone, or other substances which might with a little care have been prevented from entering the alimentary canal at all. The nature and origin of these "concretions" need elucidation The same exhibitor presented a series of Vesical Calculi from 100 patients (55 from male children under 10 years, 39 from males over 10 years, and six from females) One of these calculi contained a glass rod which the patient stated he had swallowed accidentally eight years previously, and another from a female who had been operated on three years before for vesico-vaginal fistula contained a wire suture embedded in its periphery

Thus it will be seen that the museum had a distinctly surgical tone. More than passing interest, however, attached to the 30 drawings of Dr Alfred W Campbell (Rainhill Asylum) and Dr A. C Wilson (Doncaster), illustrating the arrangement of the Medullated Fibres in the Cerebral Cortex, and they go far to justify the modern innovation of appointing pathologists to our large county asylums. The plan was instituted by the London County Council at the suggestion of Sir W J Collins, and the good work accomplished both in London and the provinces must be a source of satisfaction to all concerned.

Turning next to rarer specimens, that of Mr Walter Whitehead (Manchester) naturally occupied a prominent place It consisted of the entire right upper extremity which was the seat of lymphangiectatic elephantiasis The arm, which along with the scapula weighed 70½ pounds, was amputated from a man, aged 32 years The enlargement of the arm commenced when the patient was about eight years of age, it progressed slowly for eight years then more rapidly, and especially during the last five years The hypertrophied tissues were confined almost entirely to the extensor surface and they did not pass beyond the wrist, the hand being entirely free Dr F Craven Moore (Manchester) exhibited one of three specimens of Unilateral Absence of the Kidney, Ureter, and Testis which he had met with accidentally in the post-mortem room Dr J Dreschfeld (Manchester) exhibited an interesting specimen from a case of Hæmorrhagic Meningo-encephalitis secondary to influenza. The case, if we remember rightly, attracted considerable attention at the time on account of the symptoms, which consisted mainly of continuous sleep and vomiting A transverse section through the two hemispheres mounted by the gelatin formalin method between glass plates showed irregular capillary hæmorrhages in the cortical and sub-cortical layers and inflammatory exudation in the overlying pia arachnoid Another remarkable exhibit was that of an enormous Cavernous Angioma of the Liver by Dr A Mantle (Halifax) It had been manifest during life for two years as a gradually enlarging abdominal tumour, distinctly fluctuant and dull on percussion After death, which resulted from internal hæmorrhage (estimated at about eight pints) following an exploratory operation, the tumour was found to extend from the right lobe of the liver into the right iliac fossa, its vertical extent being 10½ inches, its width eight inches The liver and tumour weighed six pounds 13 ounces

If we except the exhibits of Dr A S F Grünbaum (Liverpool) of experimental typhoid fever in a chimpanzee and the differentiation of the bacillus typhosus and the bacillus coli communis, and of Dr Delépine of experimental tuberculosis in guinea pigs, bacteriological specimens were conspicuous by their absence It has always been a difficult matter to distinguish the highly virulent typhoid bacillus from the bacillus coli, which until lately has been regarded as non pathogenic, and the Petri dish exhibited by the first-named observer showed very clearly their differentiation by the very simple means of staining with neutral red, this colour had been taken up by colonies of the latter, whereas colonies of the former remained colourless Pathological instruments also were conspicuous by their absence, if we except a few microscopes and incubating ovens placed in a room still more isolated and difficult of access downstairs In a well equipped school like the Manchester Medical School it ought not to have been difficult to have exhibited, for instance, some of the most recent apparatus for testing and recording variations in blood pressure What a valuable educational addition from the practitioner's standpoint this would have constituted, and the objection to moving complicated mechanical contrivances over long train journeys could not have been raised in this instance

The latest methods of preparing museum specimens for educational and other purposes should always form a feature of these annual exhibitions and Professor D J Hamilton (Aberdeen) exhibited some excellent coloured casts of the lesions in typhoid fever, of the spleen in malaria, and of the kidney in tuberculosis. Dr T Shennan (Edinburgh) exhibited three life like casts in Cathcart's material (gelatin and formalin), showing a hand before and after the removal of a nævus The excellent results obtained in certain cases by this method are beyond praise.

The series of semi transparent sections of diseased hearts—which a prefatory note in the museum catalogue mentions as worthy of special attention—were interesting in some respects, but it is a questionable improvement on the older methods of mounting the organ Similar "transparencies" of morbid conditions of the lungs were also exhibited, but (as an instance of the futility of the method) it would have been somewhat difficult if the labels had been removed to have detected the difference between two specimens which were side by side—No 138, showing hyperæmia and hæmorrhage of the lung from a case of chronic alcoholism, and No 139, showing anthracosis of the lung from an old Scotch miner who had worked 40 years in a badly ventilated coal mine. This and the specimens bearing on arsenic previously alluded to were the only instances of exhibits bearing on trade diseases

The exhibits were for the most part well arranged and catalogued, and credit was due in this respect to the energy and skill of Dr Craven Moore, secretary of the museum committee, whose courtesy led us to suppose that had informal demonstrations by him at stated intervals been suggested as part of the programme they would have done much to increase the interest of those few who did find their way into the museum. But we confess to a feeling of disappointment—first, that the original idea of the founders of the museum has been allowed to lapse secondly that such a valuable means of studying nature s facts and modern methods of research and of education to the whole profession should have been relegated to an out-of the-way room on the top floor of a large and spacious building and thirdly that Manchester the very centre of trade diseases, did not place before the medical world more of her wealth of pathological material in this department.

THE HOVIS BREAD FLOUR CO, LIMITED, AND QUOTATION FROM THE LANCET

THE Hovis Bread Flour Co, Limited, of Macclesfield, have issued a small pamphlet entitled Hovis Food," or alternatively The New Foster Mother A copy of this pamphlet has been sent to us by a medical man who draws our attention to the following statement which occurs therein *The Lancet*, speaking of the prepared Hovis Food states It affords a diet lacking no physiological requirement, and by the use of these foods a milk is obtained presenting the same composition as human milk." We thereupon addressed a letter to the Hovis Bread Flour Co Limited of Macclesfield, objecting to the misuse made of our words—a misuse which will be sufficiently clear to all who read in parallel columns our real statements noting the passages put in italics, and those attributed to us

THE LANCET March 8th, 1902.	*The Circular of the Hovis Bread Flour Co Limited.*
The advantages of these foods are that they are almost entirely soluble and that *by the addition of them to diluted cow s milk* a milk is obtained presenting the same composition as human milk	By the use of these Foods a milk is obtained presenting the same composition as human milk.
It is very correctly claimed that *these foods are not complete in themselves but that their addition to milk* affords a diet lacking no physiological requirement.	*The Lancet* speaking of the prepared Hovis Food states: It affords a diet lacking no physiological requirement."

To our surprise we received a reply from the Hovis Bread Flour Co Limited, asking to have the misinterpretation of our words to which we objected pointed out. We accordingly complied with the request and have now received a further reply from the company which we subjoin.

> DEAR SIR,—In further reply to yours of the 21st ult. I have this day placed the correspondence in respect thereto before my Directors, who desire me to write confirming the explanatory letter sent to you from our Macclesfield Office on the 22nd ult. that so far as can be judged it is simply in respect to the omission from our quotation of the fact that milk should be added to the Foods that you take objection to but as you know the Hovis" Infants and Invalids Food are only prepared to be used with milk as explained in our booklets and on the directions sent out with each bottle, we therefore considered it unnecessary when quoting from your article to emphasise a fact which must be known to everybody under whose notice the Foods come.
>
> If of course, after this explanation you still consider that by continuing the quotations as we have done we are misinterpreting your meaning we will make the alterations you ask for but at the same time we think it next to impossible for anyone to be misled by the quotations as printed and we trust the matter is now settled to your satisfaction
>
> Yours faithfully
> A. E. CRESSALL, Secretary
>
> Westminster S W Sept. 1st 1902.

Our readers will see that the company do not appear to realise the gravity of the offence or the impropriety of the misquotation and our solicitors have now instructions to require the company to cease further dissemination of the misleading quotations.

BEER DRINKING IN GERMANY —According to the last issue of the Statistical Year book of the City of Berlin the annual consumption of beer in Berlin increased from 199 litres (350 pints) per head of the population in 1895 to 232 litres (408 pints) in 1900. For the whole of Germany the figures were 115 litres (202 pints) in 1895 and 124 litres (218 pints) in 1900. The average annual consumption of beer in Bavaria is higher even than in Berlin.

THE METROPOLITAN WATER-SUPPLY

THE report on the condition of the metropolitan water supply during the month of June has recently been published. It will repay study in the light of the facts referred to in the leading article which appeared in THE LANCET of August 9th, p 367 The Water Examiner states that the condition of the Thames water was good from the 1st to the 13th of the month From the 14th to the 19th, both those days included it was of bad quality, on the 20th it was of indifferent quality On the 21st, and from that date until the end of the month it was good At West Molesey the total amount of rainfall which occurred during the month was 3 76 inches. The height of the river varied from a point four inches above to one five inches below the average summer level The average daily amount of water delivered from the Thames was 125 585 077 gallons from the Lee 43,155 227 gallons, from springs and wells, 50 008,247 gallons, and from the Hampstead and Highgate ponds, 134 787 gallons. The total average amount delivered daily was 218,883,338 for a population estimated at 4 373,015, which represents a daily consumption per head of 34 35 gallons. The amount of water supplied per head was in the case of each company less than it was during the corresponding month of last year The Kent Company uniformly supplied clear water of high organic purity and of excellent quality All the samples examined of the water supplied by the New River Company were found to be clear but in the case of all the other companies waters on some occasions small amounts of superadded matters consisting chiefly of rust-coloured particles, were observed The proportion of brown tint in samples observed in a two-foot tube ranged from two to 27 degrees of the standard in use, and this it may be remarked, is a very wide range The water of the Lambeth Company exhibited the deepest average tint of brown" Samples of the water of all the companies taken on June 9th were examined by Dr T E Thorpe, F R.S. the analyst to the Local Government Board. At this date the condition of the river water was good. Later in the month there was a heavy rainfall, the height of the river rose, the water became turbid and the supplies given by some of the companies gave indications' (the nature of which are not stated) that the quality of the water was not satisfactory and Dr Thorpe made some further analyses. It may be of use to quote the exact words of his report (p 13) Owing" he says, to indications that the exceptional rainfall and consequent flooded condition of the Thames was adversely affecting some of the supplies extra samples of the Grand Junction and Lambeth companies waters were taken on June 21st, both samples were much inferior to those drawn from the respective companies mains on June 9th and the Lambeth Company s water was of indifferent quality owing to the excessive quantity of vegetable organic matter which it contained." The most important results of Dr Thorpe s examination are given in the appended table which shows the results of the analysis expressed in parts per 100 000

Company	Date on which specimen was taken.	Organic carbon	Organic nitrogen	Nitrogen as nitrates and nitrites	Total combined nitrogen
Chelsea	June 9th	0·129	0·017	0·156	0·173
West Middlesex		0·138	0·014	0·137	0·151
Southwark ...		0·151	0·017	0·133	0·150

" " ..	" 24th.	0·424	0·037	0·272	0·309
Kent	9th	0·032	0·006	0·397	0·403

The relative amount of organic impurity contained in the water examined may perhaps be most readily stated by expressing it numerically in figures. It is correctly represented as follows Kent, 6 New River 11, East London (June 9th) 21, (June 24th) 78, Grand Junction (June 9th), 24, (June 21st) 55, Chelsea, 25, West Middlesex, 26, Southwark, 28, Lambeth (June 9th), 28, (June 21st) 73 The water supplied by the Kent Company was colourless, that by the New River Company nearly colourless, the supplies of the Chelsea, West Middlesex, Southwark, Grand Junction, Lambeth, and East London Companies on June 9th were of "very pale yellow", the supplies of the Lambeth and East London Companies collected respectively on June 21st and 24th were "pale brown in colour" It is very evident from Dr Thorpe s analysis that the impurity of the Thames river water had its natural effect on the supplies given by the companies which have made insufficient arrangements for the storage of water This matter has been frequently insisted upon in THE LANCET and it has been constantly urged that more analyses should be made of the water supplied by the companies, and especially at times during which the river is in flood. *It is satisfactory to note not only that an increased* number of examinations have been made, but also that Dr Thorpe has clearly realised, and in his official capacity (*as analyst to the Local Government Board*) points out, that the badness of the quality of the water supplied is *due to the fact that the companies have made insufficient* provision for the treatment of impure river water In the course of his report Dr Thorpe says "The Lambeth Company's water was most affected. From a consideration of the records of the analytical examinations of the metropolitan waters it appears that it is 23 years since such a high proportion of organic impurity has been observed in the month of June The Grand Junction and Southwark Companies were also considerably affected for the worse, but the Chelsea and West Middlesex Companies by their comparatively large storage succeeded in avoiding the distribution of water of very high colour and excessive organic contamination." In regard to the water supplied by the East London Company Dr Thorpe states that on June 23rd it was of inferior quality and on the 24th it "contained a larger amount of organic matter than was found in any of the Thames waters" Some of the East London Company's water, we may again point out, is derived from the Thames Dr Thorpe continues "As this company possesses nearly *30 days' storage it ought to have been possible* to avoid the distribution of such unsatisfactory water on the dates mentioned" The East London Company has *no provision* whatever for the storage of its Thames supply, which in this connexion is a matter not without interest. The Water Examiner states that "all the samples of water collected at the works of the companies were efficiently filtered." It does not appear that any such samples were submitted to Dr Thorpe and it would require the ingenuity of an expert to reconcile this statement with the analyst's report, concerning the accuracy of which we have no doubt whatever

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8773 births and 4116 deaths were registered during the week ending August 23rd The annual rate of mortality in these towns, which had been 13 6 and 15 5 per 1000 in the two preceding weeks, declined again in that week to 14 4 per 1000 In London the death rate was 14 5 per 1000, while it averaged 14 4 per 1000 in the 75 other large towns. The lowest death rates in these towns were 3 5 in Hornsey, 6 4 in Willesden, 6 9 in King's Norton, 7 4 in Wallasey, 7 6 in Wolverhampton, 9 1 in Leyton, and 9 3 in Walthamstow and in Rochdale, the highest rates were 18 7 in Bristol and in Huddersfield, 18 8 in Bury, 19 2 in Merthyr Tydfil, 20 1 in Sunderland, and 20 2 in Stockton-on Tees and in Newcastle The 4116 deaths in these towns last week included 638 which were referred to the principal infectious diseases, against 579, 584, and 642 in the three preceding weeks, of these 638 deaths 263 resulted from diarrhœa, 125 from measles, 94 from whooping cough, 54 from scarlet fever, 48 from diphtheria, 47 from "fever" (principally enteric), and seven from small-pox. No death from any of these diseases was registered last week in Hornsey, Great Yarmouth, Blackburn, or York, while they caused the lowest death-rates in Walthamstow, Walsall, Rochdale, and Sheffield, and the highest in Portsmouth, Bristol, Grimsby, Liverpool, Bootle, Stockton-on Tees, and Rhondda The greatest proportional mortality from measles occurred in Portsmouth, Devonport, Bristol, Smethwick, Stockton on Tees, and Cardiff, from scarlet fever in Stockport and Burnley, from diphtheria in Tottenham, from whooping-cough in Portsmouth, Norwich, Grimsby, Wigan, and Tynemouth, from "fever" in Grimsby, and from diarrhœa in King's Norton, Liverpool, Bootle, and Rhondda Small-pox caused three deaths in London, two in Liverpool, and one each in Leicester, and in Swansea, but not one in any other of the 76 towns The number of small-pox patients in the Metropolitan Asylums hospitals, which had decreased from 1515 to 170 at the end of the 17 preceding weeks, had further declined to 128 on August 23rd, 18 new cases were admitted during the week, against 44, 21, and 24 in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, August 23rd, was 2623, against 2562, 2591, and 2595 on the three preceding Saturdays, 297 new cases were admitted during the week, against 382, 295, and 303 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 135, 131, and 159 in the three preceding weeks, declined again to 136 and were 15 above the corrected average The causes of 58, or 1 4 per cent, of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Nottingham, Salford, *Bradford*, Hull, and in 41 *other smaller towns, the largest proportions* of uncertified deaths were registered in Birmingham, Aston Manor, Liverpool, Rochdale, and Middlesbrough.

In 76 of the largest English towns 8824 births and 4319 deaths were registered during the week ending August 30th. The annual rate of mortality in these towns, which had been 15 5 and 14 4 per 1000 in the two preceding weeks, rose again last week to 15 2 per 1000 In London the death rate was 15 8 per 1000, while it averaged 14 9 in the 75 other large towns The lowest death-rates in these towns were 3 6 in Bury, 5 5 in Smethwick, 7 0 in East Ham, 7·7 in Willesden, and in King's Norton, 8 7 in Devonport and in Preston, and 8 3 in West Hartlepool, the highest rates were 20 0 in Tynemouth, 20 1 in Portsmouth, 20 4 in Sunderland, 21·2 in Bristol, 21 3 in Plymouth, 21 8 in *Bootle*, 23 7 *in Wigan*, and 24 2 in Hanley The 4319 deaths in these towns last week included 743 which resulted from the principal infectious diseases, against 584, 642, and 638 in the three preceding weeks, of these 743 deaths 371 were referred to diarrhœa, 121 to measles, 98 to whooping cough, 56 to diphtheria, 51 to "fever" (principally enteric), 44 to scarlet fever, and two to small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Bournemouth, Handsworth, King's Norton, Wallasey, Warrington, Bury, Blackburn, Rotherham, Newport (Mon.), or Swansea, among the other towns the highest death-rates from these infectious diseases were recorded in West Ham, Portsmouth, Plymouth, *Bristol, Hanley*, West Bromwich, Grimsby, and Wigan. The highest proportional mortality *from measles* was registered in Portsmouth, *Bristol, Hanley*, West Bromwich, Aston Manor, Barrow-in Furness, Stockton on Tees, Gateshead, and Cardiff, from scarlet fever in West Bromwich, Wigan, and Burnley, from diphtheria in Middlesbrough, from whooping-cough in Burton on *Trent* and in Wigan, from "fever" in Hanley, Grimsby, and Birkenhead, and from diarrhœa in Croydon, West Ham, Portsmouth, Reading, Plymouth, Liverpool, Bootle, Wigan, and Burnley Two fatal cases of small pox belonging to London were *registered last week*, *but not one* belonging to any of the 75 other large towns The Metropolitan Asylums hospitals contained 109 small pox patients at the end of last week, against numbers decreasing from 1515 to 128 at the end of the 18 preceding weeks, 11 *new* cases were admitted during the week, against 21, 24, and 18 in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2591, 2595 and 2623 on the three preceding Saturdays, had further risen to 2651 on Saturday, August 30th, 295 new cases were admitted *during* the week, against 295, 303, and 296 in the three preceding weeks The deaths referred to diseases of the respiratory *organs* in London, which had been 131, 159, and 136 in the three preceding weeks, rose again last week to 139, *and* were *nine* above the corrected average number The causes of 52, or 1 2 per cent, of the deaths in the 76 large towns were *not certified either* by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bradford, Newcastle, and in 44 other smaller towns The highest proportions of uncertified deaths were registered in Liverpool Warrington Blackburn, Halifax, Leeds, Sheffield and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 13 9 and 15 7 per 1000 in the two preceding weeks, declined again to 14 4 per 1000 during the week ending August 23rd and corresponded with the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 4 6 in Leith and 10 9 in Perth to 15 5 in Aberdeen and 17 3 in Paisley The 464 deaths in these towns included 22 which were referred to diarrhœa, 14 to whooping-cough, seven to scarlet fever, five to measles, two to diphtheria, and two to fever but not one to small pox. In all, 52 deaths resulted from these principal infectious diseases, against 46 and 64 in the two preceding weeks. These 52 deaths were equal to an annual rate of 1 6 per 1000 being 0 6 per 1000 below the mean rate from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 16 and 23 in the two preceding weeks, declined again to 22, of which 14 occurred in Glasgow six in Edinburgh, and two in Aberdeen. The deaths from whooping-cough which had been 7, 16, and 25 in the three preceding weeks, decreased again to 14 and included nine in Glasgow and four in Edinburgh The fatal cases of scarlet fever which had declined from six to one in the four preceding weeks, rose again to seven of which three were registered in Glasgow and two in Paisley The deaths from measles, which had been five and nine in the two preceding weeks, declined again to five, and included four in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 63 and 73 in the two preceding weeks, declined again to 68 but exceeded by 17 the number recorded in the corresponding period of last year The causes of 17 or nearly 4 per cent. *of the deaths registered in these eight towns were not* certified.

The annual rate of mortality in the eight Scotch towns, which had been 15 7 and 14 4 per 1000 in the two preceding weeks, further declined to 14 0 per 1000 during the week ending August 30th, and was 1 2 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in these eight Scotch towns ranged from 7 9 in Leith and 11 5 in Paisley to 15 9 in Greenock and 26 6 in Perth. The 451 deaths in these towns included 17 which were referred to whooping-cough 14 to diarrhœa, five to scarlet fever four to measles, four to ' fever and one to diphtheria. In all 45 deaths resulted from these principal infectious diseases last week, against 64 and 52 in the two preceding weeks. These 45 deaths were equal to an annual rate of 1 4 per 1000 being 1 2 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 25 and 14 per 1000 in the two preceding weeks, rose again last week to 17 of which 10 occurred in Glasgow and three in Edinburgh. The deaths from diarrhœa, which had been 23 and 22 in the two preceding weeks, further declined to 14 last week and included nine in Glasgow and two in Aberdeen. The fatal cases of scarlet fever which had been one and seven in the two preceding weeks, decreased again last week to five, of which two were registered in Glasgow and two in Edinburgh The mortality from measles showed a slight decline from that recorded in the preceding week while that from 'fever was slightly in excess The deaths referred to diseases of the respiratory organs in these towns, which had been 73 and 68 in the two preceding weeks further declined last week to 54 and were slightly below the number in the corresponding period of last year The causes of 11, or more than 2 per cent. of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin which had been 21 2, 20 2, and 19 5 per 1000 in the three preceding weeks was again 19 5 per 1000 during the week ending August 23rd. During the past four weeks the death rate has averaged 20 1 per 1000 the rates during the same period being 14 3 in London and 15 4 in Edinburgh The 142 deaths of persons belonging to Dublin registered during the week under notice corresponded with the number in the preceding week and included 23 which were referred to the principal infectious diseases against 29, 30, and 24 in the three preceding weeks, of these 16 resulted from measles, three from diarrhœa, two from whooping cough, and two from 'fever' but not one from either small pox, scarlet fever, or diphtheria. These 23 deaths were equal to an annual rate of 3 2 per 1000 the annual death rates from the same diseases being 2 5 in London and 1 8 in Edinburgh. The fatal cases of measles, which had been 20 in each of the two preceding weeks, declined again to 16 the deaths from fever' corresponded with the number in the preceding week, while those from diarrhœa showed an increase. The 142 deaths in Dublin included 29 of children under one year of age and 20 of persons aged upwards of 60 years the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a marked decline. Four inquest cases and four deaths from violence were registered and 61 *or nearly one-half of the deaths* occurred in public institutions. The causes of 13 or nearly 9 per cent of the deaths registered in Dublin were not certified.

The death rate in Dublin which had been 19 5 per 1000 in each of the two preceding weeks, increased to 20 6 per 1000 during the week ending August 30th During the past four weeks the death rate has averaged 20 0 per 1000 the rates during the same period being 14 9 in London and 14 7 in Edinburgh The 150 deaths of persons belonging to Dublin registered during the week under notice were eight in excess of the number in the preceding week and included 24 which were referred to the principal infectious diseases, against 24 and 23 in the two preceding weeks, of these, 11 resulted from measles seven from diarrhœa two from scarlet fever two from diphtheria, and two from "fever but not one from either small pox or whooping-cough. These 24 deaths were equal to an annual rate of 3 3 per 1000 the death rates last week from the same diseases being 3 0 in London and 1 1 in Edinburgh. The fatal cases of measles, which had been 20 and 16 in the two preceding weeks further declined last week to 11 while the deaths from diarrhœa, which had been one and three in the two preceding weeks further increased to seven last week. The 150 deaths registered in Dublin last week included 22 of children under one year of age and 28 of persons aged upwards of 60 years the deaths of infants showed a decline, while those of elderly persons exceeded the number in the preceding week. Nine inquest cases and four deaths from violence were registered and 72, or nearly one-half of the deaths occurred in public institutions. The causes of five, or more than 3 per cent. of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

INSPECTOR GENERAL of Hospitals and Fleets Robert Grant, C B. has been placed on the retired list at his own request. Dated August 12th, 1902.

Fleet Surgeon Richard Dormer White has been placed on the retired list, with permission to assume the rank of Deputy Inspector General of Hospitals and Fleets

Fleet Surgeon George Frederick Wales and Fleet Surgeon Alfred Thomas Corrie have been placed on the retired list at their own request.

The undermentioned Staff Surgeons have been advanced to the rank of Fleet Surgeon —William Henry Norman, James McCardie Martin, D S.O and William Maxwell Craig

The following appointments are notified —Staff Surgeons G E. Kennedy and W G Axford to the *President* for course of hospital study M J O Regan to the *Calypso* and A. S Nance to the *Britannia* for the *Isis* Surgeons S Conner to the *Britannia* for the *Isis* H. Clift to the *President* for course of hospital study and L. F Fraser to the *Wildfire*

ROYAL ARMY MEDICAL CORPS.

Lieutenant Charles F Trimble resigns his commission. Dated August 23rd, 1902. Lieutenant-Colonel A Asbury retires on retired pay Dated August 27th 1902.

The undermentioned officers of the 2nd Canadian Mounted

Rifles are granted temporary rank in the Army, whilst serving in South Africa, as follows (dated Jan 14th, 1902) —To be Majors Surgeon-Major J A. Devine, Medical Officer, and Surgeon Major H. R. Duff, Medical Officer

The undermentioned officer of the 3rd Canadian Mounted Rifles is granted temporary rank in the Army, whilst serving in South Africa, as follows (dated May 8th, 1902) — To be Captain Surgeon Captain L R. Murray, Medical Officer The undermentioned officers of the 4th Canadian Mounted Rifles are granted temporary rank in tha Army, whilst serving in South Africa, as follows (dated May 8th, 1902) —To be Major Surgeon Major C E Elliot, Medical Officer To be Captain Surgeon Captain J M Jory, Medical Officer The undermentioned officer of the 6th Canadian Mounted Rifles is granted temporary rank in the Army, whilst serving in South Africa, as follows (dated May 17th, 1902) —To be Captain Surgeon Captain D M. Anderson, Medical Officer

Lieutenant-Colonel A. L Browne will proceed to Taunton for duty on Oct. 1st Major J R. Stuart has been transferred from the Bombay District to the Nagpur District and appointed to the medical charge of the Station Hospital, Kamptee, and Major R. J D Hall has been transferred from the Nagpur District. Major F A. Shaw is to proceed to Bulford for duty The Secretary for War has approved the appointment at the Herbert Hospital, Woolwich, and Netley Hospital, Southampton, of experts in clinical pathology The necessary laboratory accommodation is to be provided. Major A. Dodd is to embark for Gibraltar early in October Major R. J Power, Major C W Johnston, Lieutenant A C Adderley, and Lieutenant T B Unwin have left South Africa for India.

The undermentioned Captains to be Majors (dated July 29th, 1902) —

Arthur E Smithson, Philip H. Watson, George L McLoughlin, D S O, Henry G Parry, D S O, Wilfred W O Beveridge, Robert W H. Jackson, Robert G W Mawhinny, George A. T Bray, Bernard Forde, and John D Ferguson, D S O

Surgeon Captain Thomas Joseph Crean, V C, from the Imperial Light Horse, to be Captain (dated Sept 3rd, 1902) —

The undermentioned Lieutenants to be Captains (dated July 28th, 1902) —Francis J Palmer, Robert A. Cunningham, Vincent J Crawford, George G Delap, D S O, William A. Woodside, Harold Simson, Harold H. Norman, William R. Blackwell, Henry M ,Nicholls, Arthur Chopping, Herbert F Hart, Arthur L A. Webb, Sidney G Butler, Lyttleton F F Winslow, John J W Prescott, D S O, Percy H. Falkner, Henry E M Douglas, V C, D S O, Ernest E Ellery, Otto W A Elsner, James William Langstaff, John L W Morris, Arthur A. Seeds, Henry S Anderson, Howard Ensor, D S O, Langford N Lloyd, D S O, Leonard Wood, Thomas C MacKenzie, Edward P Connolly, and James Henry R Bond

The undermentioned gentlemen to be Lieutenants on probation (dated Sept. 1st, 1902) ,—

Arthur Briton Smallman, Percival Davidson, D S O (from Honorary Captain), Wentworth Francis Tyndale, William Francis Ellis, John McKenzie, Arthur Herbert Hayes, Henry Joseph Crossley, Norman Dunbar Walker, William Batchelor Taylor, Reginald Storrs, George Thomas Collins, Frederick Adderley Howard Clarke, George Augustus Keppell Hart Reed, Raymond Leslie Vachell Foster, Ralph Bignell Ainsworth, Charles Augustus John Albert Balck, Gayton Warwick Smith, John Marcus Hobson Conway, Sydney Manvers Woolner Meadows, John William Smyth Seccombe, Herbert Vale Bagshawe, Charles Vivian Beresford Stanley, Dudley Sheridan Skelton, Hugh George Stiles Webb, William Walker Browne, Frederick Louis Henderson, Norman Ernest Jasper Harding, William Davenport Crawley Kelly, Richard Rutherford, and Walter Courtenay Rivers

The undermentioned Lieutenants on probation to be seconded under the provisions of Article 349, Royal Warrant Oct. 26th, 1900 (dated Sept. 1st, 1902) —William Francis Ellis and Frederick Louis Henderson.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon Major E Williams to be Surgeon Lieutenant-Colonel

ROYAL ARMY MEDICAL CORPS (MILITIA)

Sir Frederick Treves Bart, K.C V O, C B, Serjeant-Surgeon in Ordinary to His Majesty the King, to be Honorary Colonel. Mr Herbert Vaughan Craster to be Lieutenant. Lieutenant J W Hopkins has arrived in the Eastern District for duty

IMPERIAL YEOMANRY

North Somerset Dr John Empson to be Surgeon-Lieutenant Westmorland and Cumberland Dr John Livingstone to be Surgeon Lieutenant. The resignation of Surgeon-Captain J E Bowser, which was announced in the *London Gazette* of Feb 25th, 1902, is cancelled Warwickshire Surgeon Captain R. Bullock to be Surgeon-Major

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) 1st Berwick on Tweed —Surgeon Captain C L Fraser to be Surgeon Major 1st Caithness, Surgeon Lieutenant S Davidson resigns his commission

Rifle 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry Dr Thomas Douglas Brown to be Surgeon Lieutenant.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

The Aberdeen Company The undermentioned Captains to be Majors J MacK. Booth and J S Riddell. Leeds Company Captain de B Birch to be Major London Companies The undermentioned Captains to be Majors —T H Openshaw, C M G, and G S Woodhead

VOLUNTEER INFANTRY BRIGADE

Gloucester and Somerset, Surgeon Major A W Prichard, 1st Volunteer Battalion the Gloucestershire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel Geoffrey Craythorne Hall has been promoted to be Colonel Lieutenant-Colonel James Alexander Nelis has retired from the service Captain Walter Hulbert Cox has been made a Companion of the Distinguished Service Order in recognition of his services during the Mahsud-Waziri operations

The following is the list of the candidates for His Majesty's Indian Medical Service who were successful at the competitive examination held in London on August 20th, 1902, and following days —

	Marks		Marks
A T Pridham	3162	J L Lunham	2522

MR. CHAMBERLAIN AND THE WAR.

Mr Chamberlain in his recent address to the members of the Birmingham Corps of the St. John Ambulance Brigade who had been on active service with the Royal Army Medical Corps in South Africa made an interesting speech, handsomely vindicating, as he has never failed to do, the good name and humane conduct of the troops engaged in the late war This the Colonial Minister had, of course, no difficulty in doing with entire honesty As regards the allegations that were made against the concentration camp system we may incidentally cite what Mr Reitz is reported to have recently said The Boers did not, Mr Reitz stated, lay down their arms on account of the women in the camps, but on account of those who remained in the devastated country and were literally dying from hunger In the course of his speech Mr Chamberlain remarked that in cases of exceptional emergency and magnitude the Government must fall back upon the voluntary patriotism of the nation in time of war to supplement the necessary deficiencies in the regular service Notwithstanding that he had subsequently to correct a misapprehension that had arisen, Mr Chamberlain's meaning seemed to be apparent enough and correct. It would be impracticable for financial reasons to maintain permanently an army complete in all respects and of such magnitude as to meet all possible requirements But there should be no doubt about the quality and fitness for work of the regular force that is maintained and of the system by which it could be readily brought up in case of need to almost any required strength. With a well-organised Imperial system the means for meeting the military and medical needs of the Empire should be forthcoming and it is for statesmen to devise a scheme by which this can be accomplished.

THE MEDICAL SERVICES.

If we may judge from the number of candidates that appeared at the late competitive examination for the Royal Army Medical Corps, we should say that Mr Brodrick s new warrant is likely to prove attractive and to be a success. It is some time since these examinations have been really competitive, but on the present occasion we learn that such was the case, some 70 candidates having competed for 30 vacancies We trust that the War Office authorities will spare no pains to administer their medical service in such a way as to hold out continued attractions to young medical men and to secure a thoroughly efficient medical service for the army As regards the Royal Navy Medical Service we are not able to speak so hopefully Perhaps the number of young medical men with a liking for the sea and life on shipboard is smaller In any case so far as we can learn the new Admiralty regulations have failed to attract the number of candidates desired for the Royal Navy Medical Service.

DEATHS IN THE SERVICES.

Deputy Surgeon General William Stewart, A.M.D (retired) at Boldre, Lymington Hants, on August 23rd, aged 75 years. He joined the army as assistant surgeon July 29th, 1853 became surgeon July 8th, 1862 surgeon major March 1st, 1873 deputy surgeon-general Nov 27th 1879 and retired July 16th 1884 He was the author of ' Clinical Researches on the Therapeutic Action of Chloride of Ammonium in the Treatment of Hepatic Disease, and he contributed articles on its use in suppurative hepatitis to THE LANCET in 1870

Brigade Surgeon Lieutenant Colonel Robert Temple Wright, I.M S (retired), at Bedford on August 27th aged 59 years He was the author of Medical Students of the Period, and contributed articles to the Army Medical Reports and to the Indian medical periodicals

Correspondence.

Audi alteram partem."

GOLD MINERS' PHTHISIS

To the Editors of THE LANCET

SIRS —Some weeks back a communication from Dr T Oliver of Newcastle *re* Gold Miners Phthisis was published in THE LANCET [1] The Public Health Department of the Transvaal is desirous of obtaining the most complete information on the subject, and if medical men when reporting a case of death from this disease (the patient having worked in this colony) would very kindly notify this department, adding if possible, the name of the mine which employed the deceased, they would considerably assist the administration when dealing with the matter I should be much obliged if you would insert this letter in your journal.

I am Sirs, yours faithfully

G A TURNER, Acting A.M.O H.

for Medical Officer of Health of the Transvaal.

Pretoria, July 29th 1902.

THE CASE OF DR W T LAW

To the Editors of THE LANCET

SIRS,—The fund which has been so generously raised among the medical profession in aid of the heavy expenses (nearly £700) forced upon me in defending the action of Forsythe *v* Law has now been closed at a meeting most kindly presided over by Sir W S Church, Bart and though I hope to thank the kind donors individually I would ask to be allowed through your columns to offer in a more public manner my very grateful acknowledgments to all who have contributed to make it so great a success Without the help of the medical press such a result would have been unattainable and I desire to express my deep sense of indebtedness to THE LANCET for its willing cooperation, as well as for the kindly tone of the articles upon the case that have appeared from time to time in its valuable pages which judging from the many hundreds of letters received from contributors in all parts of the kingdom, have correctly voiced the general opinion of the profession in this matter as well as endorsed the comments of judge and jury when the latter stopped the case Actions of this kind are so easily brought that medical men need protection more than any other class Successful resistance tends to discourage other litigants and therefore benefits our brethren at large, and indeed the public also, for it is not to the interest of the latter that we should be fettered in using our discretion in the employment of drugs and doses in severe and intractable maladies by fear of actions for negligence. These principles have not, I think, been lost sight of by those who have so generously given in many cases of their poverty to swell the handsome total of the fund. The kindness and sympathy I have experienced from members of our calling of all ranks are such that I cannot sufficiently acknowledge them but I am desirous of publicly expressing my deep obligations to those members of the profession including men of the highest eminence, who came freely at the trial dislocating their engagements and undergoing great inconvenience in order to attend in court for four days to testify to their knowledge of the case in my behalf. It is true that very few were able to give evidence because the jury stopped the case immediately my cross-examination was ended but I am none the less grateful to the rest for their attendance and support It is unfortunately the case that I was not a member of one of the medical protection societies and as it was impossible to recover the costs awarded me I was threatened by ruinous loss. Through the generosity of the profession however this has been happily for me, averted, and I shall ever feel grateful for this help in time of need. In concluding I wish *to tender my special acknowledgments to the Presidents of* the Royal Colleges of Physicians and Surgeons and the Master of the Society of Apothecaries for the honour done me by their kindly consenting to act as trustees of the fund, and last, but not least, to my old and kind friend Dr Richard Paramore, who has freely given his time, energy and enthusiasm in my interests and whose generous efforts have been crowned with such striking success.

I am, Sirs yours faithfully

Weymouth-street W., Sept. 2nd 1902. W T LAW

HAS ACUTE ANTERIOR POLIOMYELITIS BEEN UNUSUALLY PREVALENT DURING THIS SUMMER?

To the Editors of THE LANCET

SIRS —It is generally recognised that the prevalence of acute anterior poliomyelitis increases during the summer and reaches its maximum in the month of August. During the past six weeks I have seen no less than nine acute cases of anterior poliomyelitis and I do not remember in the past seven years during which I have had charge of the out patient department having seen such a number in the same length of time. My cases have largely come from the north of London but the position of the Children s Hospital, Great Ormond street no doubt in part accounts for that distribution. My object *in writing to you is to obtain if possible,* information with regard to the observation of others on the point, and I trust that should any of your readers have observed an undue prevalence of the disease they will communicate their observations to you.

I am Sirs yours faithfully

Harley-street W., Sept. 1st 1902. FREDERICK E. BATTEN

THE CONTAGIOUSNESS OF PHTHISIS

To the Editors of THE LANCET

SIRS,—In THE LANCET of June 23rd, 1900 p. 1845, it was definitely established by Mr W Townsend Harker that to the eminent Richard Morton, M D belongs the merit of having pointed out and realised afterwards by clinical observation since the year 1689 the infectious and diffusible character of tuberculous consumption Nevertheless in some medical papers published in this country appears the error of ascribing to the French physician Villemin (Cause et Nature de la Tuberculose " 1865 and 1866 and Etudes sur la Tuberculose " 1868) so important a discovery

---

[1] THE LANCET June 14th 1902, p. 1677

For the honour of English medicine, and seeing that in our days the communicability of phthisis has become a scientific question of the first order, I beg to call attention through your columns to the subject, adding for my part that the main valuable conclusions reached by the great pathologist Morton not only were not overlooked in his time but were confirmed and corroborated by the experience of his successors whose opinions and works appeared far before Villemin, or even Kranke ("Untersuchungen und Erfahrungen im Gebiete der Anatomie," &c., 1843), who evidently preceded the former, had attempted experimental inoculations Thus v g, D L G Klein in his book, "Interpres Clinicus, sive de morborum indole," &c. (Francofurti et Lipsiæ, 1759), art. Phthisis, p 232, says clearly "Contagiosa est atque circa æquinoctia exacerbatur" Van Swieten (1764), Sennert, Valsalva, Maret, Bordeu, Baumes, and others, were also partisans of the doctrine of contagion It is known that Morgagni very rarely made post-mortem examinations of tuberculous bodies for fear of contracting the disease. Laennec and Andral, though they did not adopt entirely the views of the already mentioned authors, recommended to the healthy persons living in contact with phthisical patients several preventive measures and prohibited them from sleeping in the same room.

I am, Sirs, yours faithfully,

Zacatecas Mexico, August 4th 1902. JUAN BREÑA, M D

A QUERY IN PUBLIC HEALTH

To the Editors of THE LANCET

SIRS,—In this district the whole of a dwelling house, with the exception of a part which is used as a dairy and a room above this (dairy) which can be used as a bedroom, has been pulled down to below the ground floor and is now being rebuilt. Before it can be occupied after rebuilding is it necessary that a certificate under Section 6 of the Public Health Water Act, 1878, should be obtained? The staircase leading to the room above the dairy has been pulled down also I am, Sirs, yours faithfully,

Fressingfield August 25th, 1902 SAML. J J KIRBY

*** We should say that the facts disclosed in the letter of our correspondent amount to a pulling down and rebuilding within the meaning of the section referred to, but whether the house has been "pulled down and rebuilt" is a question of fact for the magistrates should any dispute arise and we cannot positively predict the view they would take upon the evidence which would be before them —ED L

THE DIAZO REACTION

To the Editors of THE LANCET

SIRS,—The following easy method, which I have employed for some time, might be of service to the busy practitioner A small pinch of sulphanilic acid is shaken up with a little pure hydrochloric acid in the bottom of a test tube, the urine is then added and boiled On dropping a piece of potass chlorate into the liquid the characteristic colour is found, more especially near the chlorate There may be a strong brick like precipitate to the $KClO_3$ according to the amount of reaction If very little HCl is used (one or two drops) the colour, &c, may be produced on adding pure HCl to the mixed urine, &c. If pure HCl, sulphanilic acid, and $KClO_3$ are mixed and to the milky chlorine-evolving fluid ordinary urine is added, no reaction occurs even on boiling, but if to the boiled fluid a few drops of diazo urine are added a colouration appears, more marked according to quantity If the ordinary urine + reagent fluid is neutralised by NH_3 a crystalline precipitate falls in a dark fluid, while a little of the diazo reacting urine added will at once show the characteristic colour In a narrow test-tube boiling the diazo urine with the $KClO_3$ added as in the first case produces purple adherent flakes on the surface, as well as a dark precipitate (two substances, giving by admixture the brick colour?) If to sulphanilic acid + HCl diazo urine be added and then $KClO_3$ without heat the *brick* deposit will destroy the white colour of the $KClO_3$ The urine will be coloured in a few hours In ordinary urine the $KClO_3$ remains white and the urine colour unaltered The above is probably simpler than by employing the nitrite and ammonia.

I am, Sirs, yours faithfully,

J REID, M A M D, C M Aberd.

Tunbridge Wells August 23rd 1902.

THE DANGERS OF A COMMON COLD

To the Editors of THE LANCET

SIRS,—In THE LANCET of August 16th p 419, you print a very interesting address by Dr A. Latham on "Modern Treatment of Pulmonary Consumption" in which two mentions of "catching cold" are made In one he says "By this means the body is hardened and colds are avoided", and in the other, "The windows of his (the patient's) room are then closed that he may not catch cold whilst dressing" In a discussion on the cause of a common cold that appeared in your columns last year Dr H. Willoughby Gardner[1] quoted the immunity of the inmates of open air sanatoriums as a proof that colds were due only to infection, but from these mentions of "catching cold" Dr Latham seems to imply that the immunity in these sanatoriums is due to an avoidance of contrasts of temperature rather than to the absence of an infective germ, and this is the old popular view It would be very interesting to know if patients before the "body is hardened" catch cold, and whether the closing of the windows during dressing is the result of experience, and whether any disobey the rule and suffer the penalty

I am, Sirs, yours faithfully

C CLAYTON JONES, M B Oxon

Ilfracombe, August 22nd, 1902.

LYMPH FOR REVACCINATION

To the Editors of THE LANCET

SIRS,—During the recent epidemic of small pox many persons applied to me for revaccination Being unable to obtain vaccine lymph from the Local Government Board I was obliged to get it elsewhere—viz, the Renner Establishment In this way I incurred a bill of £3 19*s* This bill in due course was presented to the guardians for payment, which they refused to entertain until the opinion of the Local Government Board had been taken This was done by me, and the Local Government Board recommended to the guardians that the amount should be paid At the last meeting of the guardians on Saturday, August 23rd, it was put to the vote, with the result that my bill was negatived by one vote, 13 for, 14 against, and six neutral. By some misunderstanding the clerk represented the bill to be £1 19*s*, instead of £3 19*s* Will you give me your opinion if it has been customary during the recent epidemic for boards of guardians to pay for lymph for revaccination, and also I should feel obliged for the names of such boards, so as to be able to put this before my board. One guardian stated that if I were paid it would establish a precedent, as if my application had been the first made for lymph.

I am, Sirs, yours faithfully,

August 1902. AN OLD SUBSCRIBER.

*** We do not remember the matter having been previously brought to our notice but in the recent epidemic of small pox at Glasgow the municipality expended £4570 for calf lymph in connexion with revaccination and it would seem only reasonable that the guardians should pay in accordance with the opinion of the Local Government Board.—ED L.

VACCINATION GRANT—Mr William Millar, public vaccinator of the Fourth (Welton) District of the Sculcoates Union, has been awarded a grant for successful vaccination for the second time in succession.

LITERARY INTELLIGENCE—"Rich and Poor in the New Testament a Study of the Primitive Christian Doctrine of Earthly Possessions,' is the title of a book by Dr Orello Gone published by Messrs A. and C Black on Sept 2nd In it the writer endeavours to interpret the New Testament teachers historically and grammatically, and to find what there may be in the spirit of their teachings that is applicable to modern social conditions He deems it no great loss if in this process the letter of their words is not in all cases found to be available. It is believed that the chapter on ' Conditions and Teachings before Christ," setting forth the humanity of the Old Testament, will be found to furnish an instructive introduction to the central theme of the book.—A new edition of Mr Sydney Stephenson's "Ophthalmic Nursing" will shortly be issued by the Scientific Press

COÖPERATORS AND THE HOUSING QUESTION

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

DURING the week preceding the meeting of the British dical Association at Manchester the Fifth International ngress of Coöperators also assembled in that town. ough it does not come within the province of this journal deal with the coöperative movement in its general sense, re are in the details of application many points that have ractical bearing on the preservation of public health If perators in so far as they are producers importers, d distributers of food can take measures to prevent lteration they will render good service in main ning the health of those with whom they deal That s, is no unimportant consideration is best set forth by following figures. During the last year the British and ottish Wholesale Coöperative Union supplied to 1,793,770 mbers through the agencies of 1462 distributive retail ieties, goods amounting in value to £52,761,175. As the ater part of these goods consisted of groceries eggs meat, on, and other eatables it will at once be recognised that s has a distinct bearing on the health of the purchasers. rther *as the members have no interest in cheating them* ves by adulterating the goods which they supply to them ves, there is in this organisation a good guarantee against injurious effects that result from unscrupulous trading t however important such considerations may be this phase the question was not brought forward at the congress ich has just been held Indeed on the present occasion delegates dealt at length with two questions that are of greatest interest to others than coöperators

Papers were read and discussions were held on the housing estion and on the increasing necessity of preventing conges n in the large towns by getting the people back to the land. ese are matters that concern the entire community from social, moral economical, and health points of view The estion was whether and how far the existing cooperative ieties could help to solve these intricate problems. Outside ranks of the coöperators themselves it is not generally own that these organisations have already done a great l in this direction Unfortunately there is so much im ovement needed that the figures submitted, though large in mselves, only meet a very small part of what is required circular was sent out to the various coöperative societies ing if they had carried out any operations in regard to se building Answers were received from 333 societies but s thought that many other societies had successful house- lding departments though they had failed to supply the ails From such information as was available—and it tes back to the year 1900—it appeared that 224 out of 333 societies had employed some of their capital to build purchase houses for their members In all, 4247 dwelling ses had been built and were owned by these coöperative ieties 3709 other houses were built and sold by the ieties and 16 082 houses had been built by members of coöperative societies on *advances made by the societies* all no less than 24,038 houses had been built by or with help of the coöperative societies This represented in h £917,397 expended by societies on the houses which y owned £827 823 on the houses which they had sold to ir members, and £3 402 308 advanced to members so as to able them to build their own houses Altogether 224 öperative societies have spent £5 147 526 in helping to use their members and by counting an average of five abitants for each house it may be said that they have ovided habitations for a population of 120 340 person

Though the above is only an incomplete record it neverthe s amply suffices to show that the coöperative movement n be, and actually is of help in dealing with the housing oblem. At the same time it may as well be at once mitted that so far it is only the easiest phase of the diffi lty that has been dealt with. It is true that the greater rt of the owners or occupiers of these houses belong to the rking classes but within that class they certainly consti te an *élite*—an aristocracy of labour As the retail co- erative societies have now in many instances accumulated ore capital than is needed to carry out their ordinary siness the investing or lending of money for building rposes has afforded a safe and yet beneficent mean disposing of such surplus These operations have been carried out in all parts of the country and members of the industrial class have thus obtained on easy terms improved and more sanitary dwellings. But in London the difficulties are greater than elsewhere, for the working men have to remove more frequently so as to follow their work To meet this two societies—the Tenant Coöperators of London and the Coöperative Builders of London—had been formed In these societies the members do not become proprietors of their houses but owners of the value of a house. For instance a man elects to live in a house The society purchases the house and this outlay is generally refunded by the occupier in the course of 14 years. He then receives a document which represents the value of the house at 5 per cent. interest. If the occupier has to leave he receives 5 per cent. interest on the capital value of the house if he remains he lives in the house rent free. But all this unfortunately applies only to men who live steady lives meet their liabilities regularly and who even if unaided by coöperative societies would still contrive to live in a fairly decent and healthy manner It is satisfactory to know that their thrift and industry are rewarded and that their position has been improved but slum land still remains a menace to our civilisation and to the public health. The question, however was raised whether the coöperative societies could not employ some of their surplus funds to provide dwellings for the extreme poor *The suggestion was greeted* with favour but nothing practical was proposed

It was in the discussion on the necessity of bringing men back to the land that there seemed to be, as matters now stand a better prospect of doing something for the poor With the aid of coöperation agricultural operations may be made to pay and this would at once draw off some of the poorer inhabitants from the large towns In many small tenancies even if the worker kept all the produce of the soil and paid neither rent nor taxes, still he would not have enough to live on in a decent manner But if a number of such small tenancies were joined together worked collectively with machinery and improved scientific methods, there would be enough for all The coöperative societies are not only capable of organising such collective enterprises, but they can dispose of the produce through their stores and supply all the needs of the agriculturists from these same stores. The enormous quantity of butter bacon and eggs exported from Denmark to England is to a large extent the product of coöperative firms, and what the Danes have done to keep their people attached to the soil could be imitated in England No large body of organised men better understand these questions than the coöperators. This is more especially the case with regard to the cooperators of the continent, for in Holland Denmark, Belgium France Italy and other countries there is a good deal of agricultural coöperation and at the Manchester congress these and many other countries were represented. From so much and such widespread experience some practical suggestions should be forthcoming What is needed is that someone with constructive ideas should gather together and assimilate the great amount of scattered information that was given in the papers read and printed. Then from what has already been successfully done in different countries he should select such portions as might be applicable to the conditions prevailing in Great Britain. This has already been attempted in Ireland where coöperative dairy farming is a growing success. In the Fens of Lincolnshire and in Norfolk there are coöperative agricultural enterprises of some promise

All this, however constitutes but a few drops in the ocean and does not suffice to prevent the fatal increase of population in the large towns with the resulting physical degeneration of the race The medical press cannot be expected to advise the coöperators as to how they should conduct their business but it is quite within its functions to applaud and to encourage every effort that may tend to procure healthy employment for a large section of the population Consequently the general tendency of the debates held at the recent international congress of coöperators may be welcomed as a sign that these influential and wealthy organisation are taking some part in the attempt to provide better homes and more outdoor healthy work for the people These efforts deserve to be watched with sympathetic interest. It is also legitimate to inquire whether the authorities have lent all the aid which can be expected where the public welfare is concerned In this respect the President of the congress Mr H. W Wolff made a regular indictment of the British Government in regard to the administration of the savings bank. A paper had been read by M Omer Lepreux, director general of the National Savings Bank of Belgium, and Mr Wolff accentuated the facts that had been brought forward by pointing out that the Belgian Savings Bank had done more, in proportion to its capital, for the housing question than any other similar public institution The British Government had appointed a committee to inquire into the working of the English Savings Bank, but had refused to receive such evidence as M. Lepreux might have given On the other hand, the Italian Government had not hesitated to follow the example given in Belgium, and the Italian as well as the Belgian workmen would now be able to obtain money from the savings banks to build more healthy homes In England, though the question had been raised in the House of Commons, the Government refused to take the matter into consideration. Yet it cannot be said that what has been done successfully abroad cannot be achieved in England, particularly as no official inquiry has been made into the matter With the help of the Belgian Savings Bank some 20,000 houses had been built, and this was a safe investment. Though the interest paid for deposits in the British Savings Bank is only 2½ per cent there are rumours current that it is proposed to reduce this low rate of interest. Surely before this is done some inquiry should be made in view of avoiding such a reduction by employing some of the money in the savings bank to build and to purchase houses for the poorer section of the community From this quarter some help in solving the housing problem may be expected, particularly as there is the example of foreign countries to show how it can be done It is difficult to explain the supineness of the British Government in this respect. The Manchester Coöperative Congress has rendered a public service by drawing attention to this subject

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

Projected Campaign of Inoculation in the Punjab —The Health of the Madras and Bengal Provinces in 1901.—Open air Treatment for Consumptives in India —The Famine —The Sanitary Progress of Calcutta —Abandonment of Lustig's Curative Plague Serum —The Plague Returns

THE Punjab Government has submitted a great project to the Government of India and the Secretary of State for sanction in order to grapple with the expected outbreak of plague during the coming winter The disease has rapidly grown in intensity in this province Commencing in 1899–1900 with two districts and one native State affected and 530 deaths, followed by the next year with seven districts and two native States affected and 6399 deaths, it had last year no less than 23 districts and nine native States attacked and over 200,000 deaths The prospect of an alarming outbreak next season has given rise to great apprehension and there is the still further danger that the disease may spread to Rajputana, the United Provinces, and other districts not hitherto involved. Experience has taught this Government, like the others, that segregation of the sick is out of the question, that evacuation of dwellings even in villages can only be partial, and that disinfection is practically useless It is curious to note that Major Dyson, sanitary commissioner of Bengal, also expresses himself with regard to the impotence of disinfection. He says in his recent report that "no marked effect on the progress of the disease followed it," that "disinfection cannot prevent fresh infection," of which there are always many chances, and that unlike inoculation it "does not confer personal immunity nor can it mitigate the severity of an attack." Finally, he says that he thinks inoculation "will ultimately be found to be the only satisfactory way of dealing with plague in the future" I have interpolated these remarks in this connexion to show the trend of medical treatment for this disease. In certain districts of the Punjab inoculation has already been accepted by the people and over 50,000 persons were inoculated last April. It has come to be looked upon as the only means possible against the disease and the Punjab Government now proposes to offer universal voluntary inoculation Arrangements are to be made to perform 6 500,000 inoculations To do this Indian Medical Service officers will be deputed from other places and special medical men will be engaged It is interesting to note that the Government will not require the services of female operators They have not been a success and the women of the Punjab will permit themselves to be inoculated by men As few natives as possible will be engaged and none below the rank of assistant surgeon Probably 37 special medical plague officers outside the Indian Medical Service will be necessary and these will be obtained if possible from England The cost of this scheme will be considerable. The special officers will get Rs 750 per mensem and expenses and the prophylactic and its carriage will cost about Rs. 2 lakhs Clerks, compounders, camp equipage, and other things will bring the cost of the whole campaign to over Rs. 8 lakhs Altogether, it is a great undertaking, but it is justified not only on the merits of the prophylactic but on the necessity of leaving nothing undone to prevent the spread of the disease to further parts and possibly overland to Europe

Two sanitary reports—viz , for Bengal and Madras—have recently been issued and it is interesting to compare the two provinces Bengal has a recorded birth rate of 38 5 and Madras only 25 1, but the latter is manifestly from faulty registration. The death rate of Bengal was 31 04, while that of Madras was only 21 3 Here again is shown the inaccuracy of registration generally in Madras The infantile death rate was very high in both Calcutta and Madras cities and in the Nilgiris the female infant mortality exceeded the male I had occasion some months back to refer to the sanitary condition of Madras city and now the Commissioner finds it necessary to ascribe the increased mortality from cholera in part to the neglect of the local authorities and to point to the imperfections of the water supply and the defective state and the inadequacy of the drainage In Bengal cholera was of moderate degree Orissa is famous for cholera, small pox, dysentery, and diarrhœa, but is curiously free from fever Behar, on the other hand, although a dry climate, reports a high death rate from fever I suspect a good deal of this was unrecorded plague. The useless practice of sprinkling wells with permanganate of potash for cholera still continues In both Madras and Bengal plague claimed many more victims In Madras the deaths rose from 895 to 3960, and in Bengal from 30,134 to 70,746 The mortality of plague cases is returned as 77 per cent. for Madras, 86 per cent for Bengal, and 91 5 for Calcutta.

The example of England and Europe in the outdoor or open air treatment of consumptives is not being neglected in India In Calcutta and many other large towns consumption is very common A home has recently been established at Hazaribagh in connexion with the Women's Friendly Society of Calcutta. At present it is only open for women and children Hazaribagh, on the Chota Nagpur plateau, stands 2000 feet up—the highest ground near Calcutta The climate is dry, the heat is never exhausting as in Calcutta, and in the winter the air is distinctly bracing The district around is said to resemble the Transvaal and Orange River colonies

The monsoon has brought some relief to the famine districts but there are still over 400,000 persons in receipt of Government assistance Bombay districts, Rajputana, Central India, and Baroda are at present the chief sufferers

The annual report of the Calcutta municipality has been recently issued and shows a record of considerable progress. The constant supply of filtered water is being extended, the water itself being good and comparing favourably with that of the largest towns in Europe The consumption is 24 22 gallons per head per day The unfiltered water supply for roads, privies, &c , is also being extended The suburban drainage is at last to be dealt with in earnest and will include a surface drainage scheme. This has been greatly wanted for many years A new vaccine depôt for the city, making Calcutta independent of Government supply for vaccine, is also arranged for Decentralisation of the work of the Health Department has been effected to a great extent by the establishment of districts Extensive changes in the *bustees* of the city have also been effected nearly 100 being taken up for improvement. A large area of ground has been purchased for a Christian cemetery outside the town, a new *dhobikhana* is in course of construction, special food inspectors have been appointed, and several plots of ground have been acquired as open spaces

After a long controversy the further manufacture of Lustig's curative plague serum is abandoned. It has never been shown even by its strongest advocates to be of much value and the Commissioner now refers to 'the very uncertain advantages of the serum as a means of treatment' He further says There has been and is available in the market at a reasonable price a serum known as Roux's serum which for the treatment of plague cases is not less efficacious than the one recently produced at Parel

The plague returns show that the epidemic is still slumbering For the week ending July 26th the total deaths throughout India were 1459 This is an increase of 359 over the previous week, but is less than the corresponding week last year Bombay accounts for 1049 deaths Madras 82, Bengal 16, United Provinces 6, Punjab 88, and Hyderabad 215. The importance of these figures lies in the fact that with the usual minimum attained at this season of the year the disease still lingers in these affected areas—it does not disappear—and as has been experienced before, it breaks out with increased virulence the next season.

August 1st

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The Queen's Hospital.

SOME important changes in the staff of this hospital are about to take place There are three surgeons and three assistant surgeons. Mr F Marsh has resigned his position as surgeon for which post there are already several candidates The claims of Mr J T J Morrison who has been on the assistant staff for 16 years, are considered as very strong while for the junior post there are at least four candidates of great merit in the field.

Little Bromwich Hospital.

This is one of the infectious hospitals under the control of the health committee of the City Council and serves an exceedingly valuable and useful purpose. At the last meeting of the City Council the recommendation of the health committee to enlarge the hospital at a cost of £16,000 was adopted The chairman remarked that the original plan contemplated 10 pavilions. Four have already been erected and opposite these there were three temporary blocks for the reception of scarlet fever patients. It is now proposed to complete the scheme by erecting three other blocks an isolation ward and a nurses pavilion. In case of an epidemic of small pox it is possible that all the pavilions might be occupied all but one are now occupied by scarlet fever cases The committee has previously used them for the treatment of typhoid fever cases, the result being an ample justification, since the mortality of that disease has been 13 per cent. as against 24 per cent. outside the institution. The authorities of the General Hospital having placed many typhoid fever cases at the disposal of the health committee the good understanding existing between the two committees has greatly facilitated the duties of each Some arrangement is desirable also for the treatment of diphtheria cases, and it is to be hoped that suitable provision will be made to meet this requirement. The subject of the treatment of infectious diseases in large centres of population at the present day is an important and at times an urgent one.

Hospital Difficulties

The annual meeting of those interested in the West Bromwich District Hospital was held on August 13th. The chairman, Mr G F Chance, reviewing the report, considered that on the whole they had reason to think that the year had been a successful one, but their income had diminished and there had been a decrease in the annual subscriptions Regret was expressed that there had been so little response to the appeal for financial help. Criticism was also levelled at the Hospital Sunday collections which exhibited a steady diminution—for instance, from £822 in 1893 to £507 for the present year The religious bodies of the community will do well to keep this plain statement of facts in mind. Another difficulty has arisen from a technical point of view Some months ago a generous inhabitant offered to defray the cost of a dental department. The board of management decided that one should be opened the cost being about £100 a year, they also appointed a dentist to fill the post. Now dissatisfaction has been expressed that this new department has been arranged without the governors first being consulted the action is declared to be illegal as no money it is said can be spent without first consulting the governors and obtaining their consent. The matter was decided at a meeting preceding the annual meeting of the governors and not reported to them, this is therefore the ground upon which some objectors base their belief that further action should be taken to test the validity of the transaction. It is well that voluntary managers however laudable their intentions may be, should keep themselves within the actual bounds of strict business knowledge.

Sept. 1st.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Food for Babes

WHAT can be done to bring some slight knowledge of what is suitable food for infants home to large numbers of our poorer women? At St. Helens it was stated at an inquest held on August 20th that a child 11 weeks old had been fed on boiled bread while a piece of meat and a piece of cinder were found in the stomach. The father had given the child a small piece of ham and the mother had given cinder tea. The verdict was Death from convulsion." probably caused by irritation set up in the stomach by undigested and unsuitable food An inquest was held recently on a child 14 months old whose parents lived at West Gorton. The mother began to give the child bread-and milk when she was three weeks old. At six months potatoes were added to the diet. In this case the mother was a hopeless drunkard and the father not much better, so that the child was dirty and neglected, squalor pervaded the whole place, and there was no clothing it all being in pawn The father had come into some money recently so that it was not a case of poverty The child died from pneumonia accelerated by diarrhœa, and was the fifth they had lost. These parent samples of many more, have most likely gone through their standards and have shared in the educational advantages which the nation has enjoyed since 1870 And with what benefit so far as the national health is concerned? For years the feeding of infants has engaged the attention of the medical officer of health of Manchester and a pamphlet of instructions has been widely distributed while the Manchester and Salford Sanitary Association has tried to spread some knowledge as to the care and feeding of infants for the last 50 years Yet such cases as those cited above are of constant occurrence. The question as to the proper feeding of children was brought up at the meeting of the Heaton Norris district council on August 21st and the distribution of pamphlets on the subject was proposed but the building sanitary and carriage committee reported against such a course It can be imagined that this conclusion would come from the building and the carriage sections of this curious combination. The gentleman who had proposed the issue of pamphlets or leaflets was not satisfied with this decision He compared the Heaton Moor East ward where the annual death rate among children under 12 months old was about 75 per 1000 with that of Heaton Mersey where it was 190 per 1000 and he thought that the committee ought to consider the matter as there must be some reason for this serious difference. One member said that there was no need of bills there They would not be read and it would be a waste of money " The chairman said that it would cost very little, and he would like a return of the num [illegible] each little house. He had had [illegible] which no doubt increased the [illegible] ceedings as these are taking place all over the country The death rate among children is discussed return are asked for and that is generally the end of the matter for the time being the death rate among the infants going on as usual.

Manchester Infirmary

At a meeting of the Royal Infirmary Board held on August 25th the chairman Sir Forbes Adam stated that one member of the board had sent in his resignation and another member would like to resign but left the matter in his hands pending any action which the board, as a board might take " As many of the 25 members were away the question was postponed and he announced that no meeting of the trustees would be called by the board before some date in October It is advisable that no hasty action should be taken for as Sir Forbes Adam said, another board should be ready to take their place if they resigned a the business of the Infirmary the convalescent home and the Royal Lunatic Asylum needed constant attention and the sub-committees appointed by the board must be ready to step into the places of those of the present board.

Blind Aid Society

The Manchester and Salford Blind Aid Society recently gave two parties of the destitute blind in the district two entertainments, one on a Wednesday and the other on a Saturday The first party numbered about 270 and included many of the poorest blind people in the two boroughs, including some from the Salford Workhouse, Hope Hospital, and Henshaw's Blind Asylum. On the Saturday the blind and their guides together were about 230, among whom were the blind inmates from the Manchester Workhouse Both picnics were held at Claremont, the residence of the Misses Heywood, whose name is one honoured in Manchester There is something pathetic in the enjoyment of these poor folks in scenes and amid surroundings unseen and, as we should think, but dimly realised. Yet there is no doubt of the pleasure they derive from such a change from the monotony of their lives. They feel the pure air and the fresh breeze and are gladdened, even in such a summer as we have been having, by the warmth of the sun. On the Wednesday they listened to the Salford Workhouse Boys' Band in the grounds of Claremont and then, headed by the band, they marched to a commodious public hall where they had tea. After tea the Bishop of Guildford gave a short address, and they returned to Claremont, listened to some more music and at about 7 P M the feeblest were sent home in carriages and the others in charge of their guides A similar programme was fulfilled for the second party on the Saturday and in better weather The band from Sir William Mather's works kindly played for their entertainment and tea this time was served under the trees Many of the blind themselves gave songs and recitations and the Bishop of Guildford again addressed them It need not be said that they had a substantial tea which they enjoyed heartily, for many of them were accustomed too often to somewhat short rations. Many of the subscribers to the society were present and waited on the blind people at their tea on the two days This society "is helping in the most practical manner a class which, though always so much in need of help, has not hitherto been adequately provided for by our local charities "

Sept 2nd.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Liverpool School of Tropical Medicine Departure of the Eighth Expedition for West Africa

THE eighth expedition of the School of Tropical Medicine, consisting of Dr J E Dutton and Dr J Todd, sailed from Liverpool on board the mail steamer *Bonny* on August 12th They are proceeding to Bathurst, the Gambia territory, and French Senegal They will be engaged on important medical research work, especially in connexion with the disease known as trypanosomiasis They will be absent from this country for about six months The researches made by previous expeditions will be of great assistance to the present one, which will continue investigations from the points reached by them. At the same time Dr Dutton and Dr Todd will make inquiries and investigations as to the general health and sanitation of the districts which they will visit. They will go further into the interior than did previous expeditions and also further into the bush. The French authorities have kindly placed quarters at the disposal of the expedition in French Senegal and have promised to give all the assistance in their power Lord Lansdowne has instructed the expedition to call on the British consul general at Dakar who will introduce the members to the French authorities The French Government was invited to attach a scientific member to the expedition, but as it had arranged to send to French West African possessions a special staff of its own for the purpose of studying the different tropical diseases there it was unable to do so M. Doumergue, Minister for the Colonies, however, added that his staff will be delighted, if occasion offers, to associate itself with the members of the Liverpool School of Tropical Medicine

Small-pox and Scarlet Fever in Liverpool Increasing Number of Cases

During the week ending August 23rd there were 42 cases of small pox in the corporation hospitals, 14 cases having been reported during the week, as against three cases in the previous week Scarlet fever cases had also increased from 541 to 567 There were six cases of typhus fever, 56 of typhoid fever, and 50 of diphtheria in the hospitals The deaths from zymotic diseases during the week numbered 49

The University for Liverpool

An intimation has been received that the Lords of the Privy Council will be prepared, early in November, to hold an inquiry and to hear counsel for or against the grant of a charter incorporating a University for Liverpool, as prayed for in the petitions of University College Liverpool, and of the committee appointed at a meeting of Liverpool citizens

Bequests to Liverpool Hospitals

By the terms of the will of the late Mr John Frederick Egner of Oakhill Park, Liverpool, who died on May 20th last, the Royal Infirmary and the Infirmary for Children participate in legacies of £500 each

Death of Mr Thomas Frederic Grimsdale, M R. C S Eng , L R. C P Edin

Mr Thomas F Grimsdale died at Hoylake on August 29th, in his eightieth year Mr Grimsdale retired from active practice in Liverpool about 10 years ago owing to failing health He was born at Uxbridge in Middlesex and moved to Liverpool in 1845 He was formerly house surgeon at the Liverpool Workhouse hospital He subsequently commenced practice in Liverpool which was principally confined to midwifery and diseases of women. He held the office of lecturer in midwifery and diseases of women at the old Royal Infirmary School of Medicine He soon developed a large and lucrative practice He was one of the pioneers in the department of gynæcology and was held in high esteem by the late Sir T Spencer Wells He was consulting surgeon to the Hospital for Women in Shaw street and also of the Ladies' Charity and Lying in Hospital. He was appointed to the commission of the peace for the city of Liverpool in 1885 He leaves a widow and a large family His eldest son, Dr T B Grimsdale, is the honorary gynæcologist to the Liverpool Royal Infirmary

The Proposed New Asylum for Lancashire Discussion at the Lancashire Asylums Board

The ever-present question of the want of accommodation for pauper lunatics in the Lancashire asylums again engaged the attention of the Lancashire Asylums Board at its meeting held at Preston on August 28th Alderman Jenkins, the chairman of the additional accommodation committee, claimed the indulgence of the board for another month to allow the committee to report He expected it would in the course of a few days come to some arrangement with regard to a site, but it would be detrimental to the board's interests to disclose matters prematurely Mr Roberts (Liverpool) said the question of having a separate asylum for Liverpool and district was being seriously considered, and if this was decided upon he did not think that an extra asylum would be required at the present time Mr Turner (Liverpool) endorsed Mr Roberts's remarks The chairman disagreed with the representatives of Liverpool and pointed out that anybody who had seen the statement as to the enormous increase in lunacy could not deny that additional accommodation was required If Liverpool built an asylum it would take five or six years to accomplish and in the meantime the need for additional accommodation would be as great as ever In the matter of the want of accommodation for dangerous lunatics it was the general opinion of the board that the evil arose from the fact that during past years they had been obliged to take in a number of chronic cases for which the asylums were not built. These cases had filled the asylums to the exclusion of acute ones Another cause of the crush in the asylums was the number of persons admitted through drunkenness who in a few months were discharged cured. Dr J M Rhodes said that another point was the necessity of amending the lunacy laws respecting grants for pauper lunatics. The condition of affairs was serious, and it was highly desirable that a petition should be sent to Parliament supported by the Lancashire Members to bring pressure on the Government to secure financial relief to the county To go on building asylum after asylum at a cost of half a million of pounds was a fearful strain upon a county If the Government would make an increased grant to enable boards of guardians to retain suitable chronic cases in the workhouses it would place the asylums in a position to deal with cases of emergency as they arose

Proposed Sanatorium for Lancashire Coronation Commemoration Scheme for the Treatment of Phthisis

The question of providing a sanatorium for the treatment of cases of phthisis arising in the administrative county of Lancaster came before the meeting of the Lancashire County Council held at Preston on August 8th. Sir John Hibbert moved the adoption of the report of the Special Coronation Committee appointed to consider the best method of appropriating the sum of £10 000 out of the county fund for the permanent celebration of the King's Coronation. Out of six suggestions the committee had unanimously decided to recommend that the whole of the £10 000 should be devoted to the establishment of an institution for the treatment of phthisis arising in the county. Sir John Hibbert alluded to the recent report of the medical officer of health (Mr. E. Sergeant) referring to the 2032 deaths caused by tuberculosis during the year 1901. The sanatorium would be to some extent self supporting. A committee was formed to consider how the scheme could be best carried out.

Infectious Hospital Accommodation at St. Helens

The St. Helens health committee have considered plans for increasing the infectious hospital accommodation at Peasley Cross by building a new pavilion and an addition to the administrative block. The plans were approved but the committee decided to inspect the sanatorium before accepting the proposal of the sub-committee, which included also the erection of a discharging block.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Notification of Pulmonary Tuberculosis in Cardiff

A SCHEME of voluntary notification of cases of pulmonary tuberculosis has now been adopted in Cardiff and a payment of 2*s.* 6*d.* or 1*s.* will be made to medical practitioners for each certificate received. In his last quarterly report the medical officer of health (Dr. Edward Walford) details some of the steps which are taken by the health department upon the receipt of these certificates. The dwelling of the patient is visited either by the medical officer of health or by one of the district sanitary inspectors and verbal instructions are given, together with a printed circular dealing with the precautions which should be taken against the further spread of the disease. Insanitary conditions such as overcrowding, want of cleanliness, defective drains, &c., are dealt with in the ordinary way as nuisances. When a death from pulmonary tuberculosis occurs or when a patient removes to another dwelling a post card is sent to the landlord or occupier offering disinfection at the cost of the corporation. In those cases where the diagnosis is doubtful or where it is otherwise desirable a bacteriological examination of the patient's sputum is made free of charge at the Cardiff and County Public Health Laboratory. During the second quarter of this year 90 such examinations were made.

The Medical Officer of Health of the Rhondda Urban District

The Rhondda urban district council has decided to appoint its medical officer of health (Dr. J. D. Jenkins) permanently instead of re-electing him annually as hitherto. The terms of his appointment will thus correspond with those of a Poor-law medical officer and he can only be dismissed from office with the consent of the Local Government Board. Although there may be some differences of opinion as to the desirability of giving to all medical officers of health fixity of tenure there can be no doubt as to the wisdom of appointing permanently those who devote their whole time to their official duties and the Rhondda council has in this respect shown itself to be very much in advance of other large towns in Glamorganshire and Monmouthshire.

Milk Supply of Newport

There appear to be still some milk dealers who are under the impression that however poor their milk may be so long as it is not diluted with water they may sell it with impunity. A Newport farmer holding this belief received a rude shock on August 29th, when the borough magistrates fined him for selling milk which contained only 2·52 per cent. of milk fat, or a deficiency of 16 per cent. on the standard. The milk was admittedly from an old cow but the magistrates contended that milk must not only be undiluted but must be of good quality. During 1901 11 milk dealers were convicted in Newport for selling adulterated milk. Six were fined £2 each, two £1 1*s.* each, two £1 each, and one 7*s.* 6*d.* In one instance no less than 14 per cent. of water had been added to the milk examined, so that if the milkman had been selling water to his customers at the price of milk for any considerable time he could well afford to pay the small fine imposed. The medical officer of health of Newport (Dr. J. Howard-Jones) in his last annual report very properly points out that in the interests of the community, particularly of the sick and of infants who are to a great extent dependent upon milk for their nourishment, it is desirable to exercise a strict supervision over the quality of the milk sold in a town.

Women Inspectors of the Local Government Board

The Bristol board of guardians is not disposed to agree with the guardians of the Chorlton union as to the necessity for appointing women inspectors of the Local Government Board. The Chorlton board has addressed a communication to the Local Government Board urging the appointment of these inspectors for the purpose of visiting girls and young children placed out by the guardians and has asked the Bristol board to give the recommendation its support with the result indicated above. The members of the Chorlton board are apparently not aware that there are already two such inspectors, one of whom was appointed 18 years ago and whose duties are very closely allied to those suggested. The reports of these two ladies, Miss Mason and Miss Chapman, are usually printed in full in the annual report of the Local Government Board and are always of the greatest interest to those connected with the Poor-law service.

Chippenham Cottage Hospital

Although the Chippenham Cottage Hospital was established as recently as the year 1899 it has already been found that the eight beds available are insufficient for the needs of the district, and at a meeting held on August 21st it was decided to enlarge the hospital building at a cost of £600.

Frome Victoria Hospital.

The trustees of the late Rev. Michael Seymour Edgell of Swanley, Kent, have allocated about £1000 to the committee of the Frome Victoria Hospital. Mr. Edgell left his residuary estate to be divided between 11 persons and institutions, one of the latter to be a hospital in England to be selected by his trustees. The present hospital was opened last year and was erected to commemorate the Diamond Jubilee of Queen Victoria.

Clevedon and Walton Dispensary

The thirty-eighth annual report of this institution which has just been issued shows that during the past 12 months 673 patients had been attended. The financial statement was satisfactory. The committee records with much regret the death of Dr. S. Skinner after 30 years' service on the honorary medical staff.

Richmond District Lunatic Asylum

AT the monthly meeting of the joint committee of management of the Richmond District Lunatic Asylum held recently a report was received from a special committee appointed to consider the question of the medical staff. The committee recommended that it could not at present advise any increase in the number of the permanent medical staff. In connexion with the resignation of Dr. D. F. Rambaut it made the following recommendations:—

> That Mr. O'Conor Donelan remain as at present at Portrane as deputy resident medical superintendent; that Mr. Collinan remain in his present position as second medical officer; that Dr. Fleury be advanced to the position of third medical assistant officer; and that Mr. Redington be advanced to the position of fourth assistant medical officer and, moreover, be appointed to the position hitherto held by Dr. Rambaut.

The Diseases Notification Act

The authorities in Dublin have at last determined to put in force the Act for the Compulsory Notification of Infectious Diseases. On August 22nd at the Southern police-court a fine of three guineas with two guineas costs was imposed in the case of a dairyman who neglected to notify that his children were suffering from scarlet fever in July.

Lurgan Urban Sanitary District

The report of the medical superintendent officer of health of the Lurgan Urban Sanitary District (Dr Samuel Agnew) for the year 1901 has just been issued The town of Lurgan (the fourth town in Ulster) has been, as regards health, in a satisfactory condition during the year 334 births and 217 deaths were registered, which constitute a birth-rate of 28 20 and a death rate of 18 6 per 1000 The death-rate is 3 5 below the average of the previous 10 years and the birth-rate 5 0 lower The zymotic death rate was 1 4 per 1000 The notification of infectious disease has been a great success, and when the suitable disinfecting chamber is ready it will be an enormous help to the authorities in the union. During the months of August and September there was an outbreak of dysentery—due, Dr Agnew thinks, to the insanitary state of the property upon which it originated. Of the total number of deaths (217) registered 30 were due to pulmonary tuberculosis, or double the number of those who died from all the recognised infectious diseases combined Dr Agnew, in addition to all the other well known measures to prevent pulmonary tuberculosis urges the improving of the conditions under which the people, especially the working people, live Healthy houses, properly ventilated, with modern sanitary arrangements, are most necessary to render the people better able to withstand the attacks of the tubercle bacilli. This report, which is an interesting one, shows that the public health of Lurgan is well looked after by Dr Agnew

The British Association.

Preparations for the visit of the British Association to Belfast are proceeding rapidly The first meeting will be on Sept 10th, when Professor Dewar, the President, will give his opening address

Queen's College, Belfast The President's Report for 1901–1902

The report of the President of Queen's College, Belfast, for 1901–1902, has just been issued Reference is made to the very regretted resignation of Professor Purser, who, in addition to his duties as lecturer on mathematics, was for many years registrar of the college Mr A C Dixon, senior wrangler of 1886, has been appointed his successor Two other blanks have been left in the professorships through the resignation by Professor W H Thompson and Dr R. O Cunningham of the chairs of physiology and natural history respectively So far their successors have not been appointed. Through the munificence of Sir James Musgrave, Bart., a chair of pathology has been provided (to which Dr J L Smith has been appointed), and it is expected that the new physical laboratories (the gift of the Right Hon W J Pirrie) will soon be erected, and a new organ has been promised by Mrs W O Mitchell. Reference is also made to the honours conferred on members of the teaching staff and to the distinctions gained by students at the Royal University examinations A short reference is made to the meetings in Belfast of the University Education (Ireland) Commission, the report of the evidence of which the public in Belfast are every day expecting to see.

Health of Belfast

At a meeting of the city corporation of Belfast, held on Sept. 1st, it was reported that the death-rate of the city kept low (16·9 per 1000 from all causes), much lower than in the corresponding period of the previous year During the period between July 20th and August 16th, 195 cases of zymotic disease have been notified (105 of typhoid fever, 35 of simple continued fever, 22 of erysipelas, 13 of diphtheria, nine of scarlet fever, seven of puerperal fever, three of small pox, and one of membranous croup) A very extraordinary discussion took place as to the notification of infectious diseases It would appear that the medical superintendent officer of health (Dr Henry Whitaker) was instructed by the public health committee to look into the question of the notification of a number of typhoid fever cases in No 2 hospital district during the week ended August 2nd, his instructions being to see the patients and to ascertain from them the nature of the diseases they were labouring under As a result he reported (after his personal inquiries) that in the case of 17 of them the patients were suffering from measles, bronchitis, pneumonia, alcoholic delirium, gastric fever, cold, or some malady other than typhoid fever A copy of this report was ordered to be sent to Dr John Barron, the medical practitioner who notified the cases, who in his reply points out that it was due to him that the medical officer of health should have met him in consultation He said that the medical officer of health seemed to have received his information from the patients themselves or from their relatives who had no special knowledge in diagnosing disease The fact that some of the patients were certified to have been suffering from bronchitis, measles, &c., did not prove (Dr Barron thought) that they were not suffering from typhoid fever also, as is frequently the case. His custom was to report a case at once, knowing the danger of typhoid fever spreading in epidemic form. He said that if in the future a question should arise as to the diagnosis of disease contained in his notifications he would be happy to accompany the superintendent officer of health and to afford him any information he wished concerning the case, but he protested against his going behind his back, a course at once unsatisfactory and unprofessional. After a long discussion it was decided to refer back to the public health committee, to make a finding thereon for submission to the council the report of No 2 hospital district with the reply of Dr John Barron.

Death of Mr William Park Blair, L R C P Edin., L F P S Glasg

I regret to announce the death of Mr Blair, which occurred on August 31st, at his residence, Ballynure, co Antrim, after a very short illness. The deceased was the sixth son of the late Dr Crawford Blair and succeeded his father as medical officer of Ballynure dispensary district. He received his early education in Scotland under his uncle, the Rev J Blair of Lockerbie, and subsequently studied at Glasgow and Edinburgh He had an excellent practice and was greatly respected by his patients He was interred on Sept. 2nd in Ballynure burying ground, a large concourse of friends and patients by their presence testifying to their respect for him

Lady Hermione Blackwood as a Nurse

During the last month Lady Hermione Blackwood, daughter of the late Marquis of Dufferin and Ava, has been acting as locum tenent for the nurse of the Bangor District Nursing Society She discharges all the duties required and prefers to be known as Nurse Blackwood Lady Hermione received her training at the London Hospital

County Cork Branch of the Irish Medical Association

At a meeting of the council of the County Cork branch of the Irish Medical Association, held on August 30th at 74, South Mall, Cork, it was decided, for the guidance of candidates for Poor law medical appointments in the county and city of Cork, to call their attention through the press to the following recommendations adopted by the Irish Medical Association in reference to these appointments and to impress upon them the advisability in their own interests of abiding by the decision of the council of the association —

1 We recommend after full consideration that £200 per annum be fixed as the minimum salary for any dispensary appointment, and £120 per annum for any workhouse appointment unless held jointly, when £300 should be the amount for both, and we suggest that these amounts be decided upon as reasonable

2. That all medical salaries should be subject to a quinquennial increment either based on the Civil Service scale or at a fixed percentage rate

3 A yearly holiday of one month as a right, with well-defined rules as regards the appointment and payment of a substitute

4 Superannuation on Civil Service scale as a right.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Museum of the Assistance Publique

M MOURIER, director of the Assistance Publique, to whose sudden death I refer in my next paragraph, had intended to start a museum in connexion with the Assistance. If M Mourier's idea is carried out the proposition passed some 20 years ago by the municipal council will be realised M Mourier had intended to take for the purpose of housing his museum two or three rooms in the new buildings of the Assistance on the Boulevard de l'Hôpital. The museum will include sundry objects of art, sundry historical objects, and a number of interesting manuscripts which up to now have been scattered throughout the various hospitals and which certainly ought to be preserved Prominent among the objects to be exhibited are Fouquier-Tinville's desk at which he used to work and an instrument-case belonging to Dupuytren, the instruments have elaborately carved ivory handles and are thus regular nests of microbes From the Hôtel Dieu come two magnificent porcelain vases given by Napoleon I. to the hospital a bust in hammered iron and a small Renaissance coffer Finally there is a register of abjurations in which are inscribed the names of all Protestants who before they could be treated in the hospital had to abjure their Protestantism. There is also a remarkable collection of medicine-jars and the like of the seventeenth century From the Charité Hospital come three very fine antiphonaries, and among the pictures—of which there are a good many—is a portrait of the Chancellor D Aligre and another of the Comtesse de Lariboisière. Some curious documents are also preserved, among them being the *acte d'abandon* of the foundling Jean Lerond afterwards known as D Alembert, the great mathematician

The late M. Mourier

M Mourier the Director of the Assistance Publique, died very suddenly at the age of 44 years. He was *Chef de Cabinet* to M. Cazot in 1881 and to M. Ferrouillat in 1889 both of whom were Ministers of Justice. In 1896 he was made a member of the Conseil de Surveillance of the Assistance Publique and at the death of M Napias he was asked to take his post which after some hesitation he accepted. Having a large private fortune he refused to receive the salary of 15 000 francs. M. Mourier made up for his want of medical knowledge by a wonderful talent for administration, and the two ideas he had at heart were first, the reform of the hospital staffs—that is to say the substitution of female nurses for male and the separation of the non medical staff into two well-defined classes—namely, the proper hospital staff who were simply to look after the nursing of the patients and the general staff who were to look after feeding cleaning commissariat, and the like. The second project which he had in mind was the rebuilding of all the old hospitals and to carry out this latter work he wanted to enlist the aid of competent medical men and architects so that the hospital should be built by people having a complete knowledge of hygiene and hospital organisation. His early death has unfortunately occurred before these ideas could be carried out, but it is to be hoped that they will not disappear altogether on this account

A Judicial Error

A pharmaceutical chemist named Danval, was condemned some 20 years ago by the Court of Assizes for poisoning his wife His sentence was 20 years penal servitude. His friends however were convinced of his innocence and by no means agreed with the report of Dr Bergeron, the expert in forensic medicine, upon which Danval was mainly condemned and this opinion was by no means weakened when it became apparent that Dr Bergeron had for some time given evidence that he was suffering from cerebral weakness. A committee was formed to demand the revision of the sentence and on the committee were many pharmacists and medical men among whom were Professor Cornil a member of the Senate, and Dr Galippe. After an agitation carried out for a long time the committee obtained from the President of the Republic a pardon for Danval, and the Court of Cassation re-examined the evidence and decided that Danval was innocent. Danval accordingly left New Caledonia and has just returned to Paris, where he received a great reception at the station from members of his committee and from many students in pharmacy As the unfortunate man has no money Professor Cornil and Dr Galippe are trying to get him some employment at the hospitals

NEW YORK

(FROM OUR OWN CORRESPONDENT.)

Delay of a Telegram to a Physician in a Confinement Case

THE Supreme Court of Nebraska has affirmed, on a commissioner's opinion in Western Union Telegraph Company v Church, a judgment for $960 damages against the company for a failure promptly to deliver a telegram addressed to a physician saying Come to *L. C Church's at once. L. C Church.*" The message was delivered to the company for transmission at about 6 P.M. and was delivered at about 9 P.M. of the same day It had been previously arranged with the physician to attend a confinement case in that family and he started immediately upon the receipt of the telegram but did not arrive until after the birth of the child, a foot presentation " during which the child died. In the commissioner's opinion it was clear that the telegram itself addressed to a physician—one known to be such by the agent of the telegraph company at the place of delivery—was sufficient to apprise it of the necessity of prompt delivery It could not be supposed that a message of the character of the one in question should specifically set forth the actual conditions calling for the physician's presence the person who was sick, or the nature of the disease, and it was not necessary that this should be done in order to apprise the company of the need promptly to deliver the message There was no doubt that the labour during confinement was prolonged on account of the failure of the physician to attend and the party suing was entitled to substantial rather than nominal damages. Nor was the verdict excessive. That great pain and agony ordinarily accompany childbirth, even in cases where sympathetic and competent persons are in attendance to render all assistance lying within human power is a matter of common information. It may be said that this pain and agony are such that no person could negligently be the occasion of its prolongation without being culpable

Uniform of the Medical Department of the Army

A board of officers appointed to revise the uniform of the army has changed the insignia of the Army Medical Department and the Hospital Corps from the cross to the caduceus. This device is not only very sightly but is also particularly appropriate for the medical service of the army the rod signifying power the serpents healing and the wings diligence and celerity The matter of uniformity also was considered by the board, since in almost every foreign army the caduceus is used as the insignia of the Army Medical Department Still another reason for the change from the insignia of the cross to the caduceus is the fact that the former device is used by various relief organisations not under military control which fact caused much confusion in the popular mind as to the identity of the Army Medical Department and the Hospital Corps during the late war with Spain. The board further proposes to change the colour of the Army Medical Department from green to magenta this change is likewise in conformity with the customs of foreign nations superficial examination proving that dark red magenta, or maroon is the distinctive colour not only of the Medical Department of our own Navy but also of 13 of the most important armies of the world including those of England, Germany France, Austria, and Russia. The proposed changes will add much to the attractiveness of the uniforms of our medical corps the combination of blue and magenta is very rich and sightly while green and blue were quite the reverse. This same board is making other changes in the uniform as a whole, particularly with regard to the uniform of the soldier for field service these changes being conducive to greater comfort, hygienic advantage, and practical utility under the conditions of modern warfare

Regulation of the Sale of Virus

The Commissioners of the District of Columbia propose to regulate by law the sale of viruses serums toxins and analogous products. The Bill provides that the surgeon general of the army the surgeon general of the navy the supervising surgeon general of the marine hospital service, the chief of the Bureau of Animal Industry and the health officer of the District of Columbia shall constitute a board with authority subject to the approval of the Secretary of the Treasury to promulgate from time to time such rules and regulations as may be necessary in the judgment of that board to govern the issue suspension, and revocation of licences for the maintenance of establishments for the propagation and preparation of viruses serums, toxins and antitoxins and analogous products applicable to the prevention and cure of the diseases of man intended for sale in that district or to be sent, carried, or brought from any state, territory or the District of Columbia into any other state, territory or the District of Columbia or from the United States into any foreign country or from any foreign country into the United States. All licences for the maintenance of establishments for the propagation and preparation in any foreign country of any virus serum, toxin antitoxin or product aforesaid for sale barter or exchange in the United States shall be issued upon condition that the licentiates will permit the inspection of the establishments where such articles are propagated or prepared in accordance with this law

August 2[illegible]th

Obituary.

ALFRED COLEMAN, F R.C S ENG , L R.C P LOND , L.D S

WE regret to announce the death, from apoplexy, of Mr Alfred Coleman on August 26th Mr Coleman was born on Dec 30th, 1828, at Wandsworth, his father being of a Quaker family He was educated at St. Bartholomew's Hospital and became a Member of the Royal College of Surgeons of England and a Licentiate in Dental Surgery in 1860 In 1866 he obtained the diploma of Licentiate of the Royal College of Physicians of London and two years subsequently was admitted a Fellow of the Royal College of Surgeons. He devoted his professional life to the practice of dental surgery and was ever keenly interested in all that appertained to its progress, both scientifically and socially His name appears in the first list of members of the Odontological Society of Great Britain. His contributions to the Transactions of the society were numerous and valuable the more important being "The Nature of Dental Caries," "Anæsthesia considered especially in Reference to Dental Surgery," "Cystic Tumours," and "Forms of Irregularity of the Teeth and their Treatment." He became President of the society in 1877 and on his retirement from practice was made an honorary member He was the author of "A Manual of Dental Surgery and Pathology," and in addition contributed articles to THE LANCET, *Medical Times and Gazette*, *British Medical Journal*, &c Mr Coleman was for many years dental surgeon to St Bartholomew's Hospital and Lecturer on Dental Surgery in the medical school He was also President of the Abernethian Society For several years he held the post of Lecturer of Dental Surgery to the Dental Hospital of London and was also an Examiner in Dental Surgery for the Royal College of Surgeons of England. He took a keen interest in anæsthesia and was one of the first dental surgeons in this country to employ nitrous oxide extensively in practice. He devised a mouth opener which was the "father" of the modern "Mason" gag, and with Mr Clover he experimented with methods for prolonging anæsthesia in dental operations, and the present method of prolonging nitrous oxide anæsthesia by the nose piece has been evolved from his original ideas Mr Coleman commenced practice in Finsbury square and subsequently entered into partnership with Mr Samuel Cartwright at Old Burlington street At the expiration of the partnership he practised in Savile row and was associated in practice with Mr F Ewbank and Mr J Ackery Owing to failing health he retired to Streatham, where he still carried on a small practice, but this even proved too much for his health and in 1884 he emigrated with his family to New Zealand, where he remained for six years While in New Zealand he took especial interest in municipal affairs and was appointed surgeon to the New Zealand Defence Forces After his return to England in 1890 his old hospital attracted him once more and he took a great interest in its administration, becoming a governor and subsequently almoner to the hospital.

WILLIAM HENRY HAYWARD, M R C S ENG , L S A.

MR. W H HAYWARD died on August 6th from heart disease in Manchester where he had latterly practised His medical education was received at Queen's College, Birmingham, during which early period of his career he displayed much diligence and ability, taking a good position in the various classes and coming out first prizeman in clinical medicine and clinical surgery He was admitted M R.C S Eng in 1856 and subsequently took the additional qualification of L S A Among his first appointments he held the positions of house surgeon at Queen's Hospital and prosector of morbid anatomy For many years he practised at Oldbury, of which place he was the first medical officer of health, his tenure of the appointment continuing for 12 years Mr Hayward took a great interest in geology and wrote many papers on the subject, one of them, published in 1864, related to the discovery of remains of the *Elephas primigenius* at Oldbury A man of artistic, literary, and musical tastes he was a most genial companion, and his death is much regretted by all who had the pleasure of knowing him At the time of his death Mr Hayward was in his sixty eighth year, he was a widower and has left a large family

Medical News.

UNITED KINGDOM POLICE SURGEONS' ASSOCIATION —The annual meeting of the United Kingdom Police Surgeons' Association was held at Manchester on July 30th. There was a good attendance of members, including Dr H W Oulton (chief police surgeon of Dublin and Vice President of the association) in the chair, Mr J Chronnell (Hindley), Dr J F Craig (Birmingham), Mr R. J Dearden (Manchester), Mr H. Nelson Hardy (London), Surgeon-Major G Harrison (Chester), Mr F W Lowndes (Liverpool), Mr J T J Morrison (Birmingham), Surgeon Major W M Roocroft (Wigan), and Mr T Wolverson (Wolverhampton), and one visitor, Mr A. N Davies (Liverpool) Apologies for non attendance were received from Mr J Paul Bush, C M.G (Bristol), Dr H Barnes (Carlisle), Mr W J Heslop (Manchester), and Dr L Maybury (Portsmouth) The minutes of the previous annual meeting were read, confirmed, and signed. In its annual report the council drew attention to the continued efforts being made by this association in conjunction with the British Medical Association to obtain a more adequate scale of fees for medical witnesses in criminal cases Early in the present year, as a result of the exertions of Mr W F Lawrence, M P, and the interest taken by other members of the House of Commons, the Home Secretary appointed a departmental committee with Sir John Dorington, M P, as chairman, to report upon this long standing grievance of the medical profession Mr F W Lowndes and Mr Nelson Hardy in giving evidence before this committee showed that the expenses incurred by medical men in attending assizes frequently exceeded the fees payable under the existing code which was passed as far back as 1858, they also pointed out the increasing reluctance of the profession, for the foregoing reason, to examine cases of alleged criminal assault, and they mentioned the instances which had occurred at Hindley in Lancashire and Bungay in Suffolk where the medical practitioners had declined to examine such cases. The opinion expressed to the committee was that for each case the minimum fee should be one guinea per diem in magistrates' courts and two guineas per diem in assize courts and quarter sessions The matters dealt with in the report of the council were discussed by Mr Dearden, Mr Nelson Hardy, Mr Chronnell, Mr Roocroft, Mr Lowndes, Dr Oulton, and Mr Morrison, and it was unanimously resolved that the report should be received, adopted, and entered on the minutes —It was proposed by Mr Morrison, seconded by Mr Lowndes, and resolved unanimously, "That in the opinion of this association the medical practitioners of Bungay, having previously notified their intention to the police on stated grounds, were justified in declining to examine the case of alleged indecent assault referred to in the summer assizes held at Bury St. Edmunds, and this association is further of opinion that the subsequent animadversions of the Home Secretary, Mr Ritchie, were uncalled for, in view of the fact that whereas the authorities of the Home Office have acknowledged the hardship inflicted on medical witnesses in criminal courts by the existing scale of fees they have nevertheless repeatedly refused to increase the rate of remuneration"—The treasurer reported that the accounts had been duly audited, a favourable balance of £36 5s 9d being shown —The report of the revision sub committee, which had been approved by the council, was adopted. The alterations affect Rules 4, 7 and 11, and enact that the number of vice-presidents shall be two or more, that four members of council shall form a quorum of that body, that a general meeting of the association shall be held during the annual meeting of the British Medical Association, and that the retiring president shall be eligible for re election —The following officers were elected for 1902–1903 —President Mr J Paul Bush, C M G (Bristol) Vice Presidents Sir Henry D Littlejohn (Edinburgh) and Dr H W Oulton (Dublin) Treasurer Mr H Nelson Hardy (London) Honorary Secretaries Mr F W Lowndes (Liverpool) and Mr J T J Morrison (Birmingham) Council Dr H. Barnes (Carlisle), Dr J F Craig (Birmingham), Mr W J Heslop (Manchester), Mr E K Houchin (London), Dr L. Maybury (Portsmouth), Dr D McDonnell (Belfast), Mr W Powell (Cheltenham), Mr H. W Roberts (London) Mr W M Roocroft (Wigan), Dr C Templeman (Dundee), Dr T Wallace (Cardiff) and Mr W Washbourn (Gloucester) Representatives on Joint Committee for Medical Witnesses

Fees Mr Nelson Hardy Mr Houchin, and Mr Roberts.—Votes of thanks were accorded to Dr Oulton for presiding and to Mr Heslop for his kind hospitality to the association

Centenarians —It is announced that Mrs Rebecca Binks of Doncaster has celebrated the 103rd anniversary of her birthday She was born at Epworth, the birthplace of John Wesley on August 28th, 1799 —At Leyland, on August 23th Mary Mabon died at the residence of her daughter in Hough lane at the age of 103 years. The deceased who formerly lived at Bolton, had been bedridden for nearly three years. She could remember the reign of George III.

The Development of Cheltenham as a Spa.—For many years past Cheltenham has made spasmodic efforts with a view to the resuscitation of its natural mineral waters, but with little success. While the town council has been dallying with the question Mr H. Cronheim who is temporarily residing in the town, has recognised that Cheltenham has a valuable property in its mineral waters, and at the meeting of the town council a proposal was submitted by him Being impressed with the value of the waters he has approached several wealthy friends with a view to form a syndicate for the purpose of developing the waters, and he applied for an option for six months (for which he would pay 50 guineas) to acquire for a period of 50 years the whole of the Cheltenham mineral waters in the possession of the corporation in consideration of an annual payment and upon terms to be agreed upon. He also asked if the corporation would be prepared to let to him on lease the Winter Gardens for the same period. The council discussed the question at some length, and it was intimated that probably £200 000 to £300 000 would be spent on the enterprise. The council by resolution, expressed its willingness to comply with the application provisionally upon terms being arranged.

Congress on the Treatment of the Insane —The International Congress for the Improvement of the Condition of the Insane was opened at Antwerp on Sept. 1st, under the presidency of M. van den Heuvel, Belgian Minister of Justice.

Victoria Cottage Hospital, Abergavenny —The ceremony of declaring this hospital open will be performed by Lord Tredegar on Oct. 6th.

New Cottage Hospital at St Andrews —A new cottage hospital which was opened on August 27th at St. Andrews contains a ward forming a memorial to the late Lieutenant F G Tait, son of the late Mr Peter Guthrie Tait, professor of natural philosophy in Edinburgh University A tablet in marble bears the following inscription written by Mr Andrew Lang —

> In memory of Frederick Guthrie Tait Lieutenant 2nd Battalion Royal Highlanders (Black Watch) wounded at Magersfontein killed in action at Koodoosberg February 7 1900 aged 30 years. The wing of the hospital was erected by subscriptions from 145 golf clubs and a wide circle of friends by whom he was beloved for his manly and honourable character and admired for his pre-eminent skill in the game

At the last meeting of the Southend-on Sea town council the medical officer of health Dr J T C. Nash, was voted an honorarium of 125 guineas in recognition of his services in connexion with small pox

Rochdale Infirmary —On August 29th, at a meeting of the Rochdale Infirmary committee a letter was read from Mr James Ogden of Kilnerdeyne Terrace offering £1000 as a birthday gift on the occasion of the donor's seventieth birthday

Grimsdale.—On August 29th at Sandycroft Hoylake Thomas F Grimsdale L R C P Edin M R C S Eng in his 80th year

McFarland —At the Royal Hospital Sheffield, on August 30th George McFarland M.B Ch.B Edin of Hawera, New Zealand.

N.B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

A CORONER AND PATENT MEDICINES

SOME strong and sensible remarks of Mr John Troutbeck upon the dishonest statements advertising quack remedies deserve more attention than they are likely to receive. The case which came before the coroner on August 22nd was that of a child who had died from convulsions for which the mother had treated her with a patent medicine. According to the label on the bottle its contents were a "lightning cure for all kinds of coughs," cured various ailments, and destroyed the germs and bacilli of consumption. It is little to be wondered at that the poor fall easy victims to the specious blandishments of these quack remedies. It is perhaps, more surprising that, as Mr Troutbeck remarked the Government make money out of dishonest advertising" There is little doubt that the Government stamp upon bottles of the kind in question goes far to confirm the favourable impression wrought in a poor woman's mind by the grandiloquent claims of the vendor's label. In the particular case to which we refer the coroner declared the "cure harmless. Often such is not the case but even if actually harmless in themselves these medicines do an infinite amount of harm by deferring or preventing the poor from seeking more trustworthy aid How long will it be before the law recognises the unsatisfactory condition respecting the sale of poisons or of quack medicines?

A FATAL CASE OF BELLADONNA POISONING

A PARTY of children from Portsmouth, spending a holiday in West Sussex ate a number of berries from the plant of the belladonna, or deadly nightshade." They were taken ill soon after one a boy aged 11 years who had eaten more freely than the others, seriously All showed the usual symptoms—flushed face, dry throat and skin, the latter covered with a scarlatiniform rash, rapid pulse widely dilated pupils and a restless delirium In the case of the boy an emetic did not perform its work for some time and he never recovered from the effects of the poison, death ensuing a few hours later Evidence at the inquest showed that the other children would have eaten more of the fruit but for the peculiar sweet flavour

A HOLIDAY WITHOUT RAIN

To the Editors of THE LANCET

SIRS —In offering some consolation to your readers for the badness of the summer you observe that had they gone abroad they would have fared no better May I say that I have had a month's holiday without a drop of rain except a slight drizzle one morning? I sailed from Liverpool at the end of June and returned at the end of July having had a fortnight in the Canary Islands. Though this was not the best time of the year for the islands it was never oppressively hot and the sea voyage was delightful As I took the trip for the benefit of my wife's health it occurred to me that medical men would be interested in knowing that it can now be done very cheaply Messrs Elder Dempster and Co issue a £15 ticket which covers first-class voyage to Grand Canary and back (about a week each way) and a fortnight's stay at the Hôtel Métropole at Las Palmas The hotel is a very pleasant one on the verge of the sea.

I am Sirs yours faithfully

August 28th, 1902. JAS. SYKES

OBJECTIONABLE ADVERTISEMENTS.

A CORRESPONDENT has sent us a copy of the August issue of the *English Illustrated Magazine*, which is published by Mr T Fisher Unwin, and asks our opinion of certain advertisements which appear in this popular periodical. The advertisements in question include one of Mr T R. Allinson's Book for Ladies" the character of which may possibly be well known to our readers; one of a book entitled "A Book for Wives which is published by Messrs. D Haddon and Co., surgical appliance makers of Ipswich and which according to the advertisements contains "golden information"; and one of a book entitled "Confidential Talks with Husband and Wife purporting to be written by an M D whose name does not appear on the Register and having for its sub-title the words, A Book of Information and Advice for the Married and Marriageable" The advertisement sets out that the last book, which is published by Messrs. Oliphant Anderson and Ferrier of Edinburgh deals with such pleasant subjects as Love's Consummation The Relative Amorousness of Males and Females "The Limitation of Offspring" and Old Age and Sexuality We can only express our surprise that a publisher of Mr Fisher Unwin's standing should sanction the appearance in any publication issued from his house of such advertisements.

THE MAN IT WAS THAT DIED

THE list of accidents from motor-cars bids fair to rival the casualty lists of a fair-sized campaign In most cases it is some sort of consolation to observe recklessness and ignorance play a large part in bringing about the catastrophe An unfortunately large proportion of accidents however appears to be unavoidable under the present conditions of roads and of motor-cars. Of such are the cases in which a break properly applied to a car going at no improper speed causes skidding and an accident. Perhaps in the category of unavoidable accidents may be classed the running-over of a couple of dogs fighting in the road An accident of this nature at Rottingdean recently led to the death of a farm labourer named Moffett. The deceased was sitting on a bank beside the road and his dog was fighting with another when a motor-car travelling only eight miles an hour ran into the dogs overturned and injured Moffett's leg He was treated at the Sussex County Hospital, when after 12 days tetanus set in and in spite of all treatment proved fatal

A QUESTION OF FEES

To the Editors of THE LANCET

SIRS,—A and B are both away from their separate practices and are friends; each leaves a locum tenent in charge—C and D—who are strangers to each other *C asks D to apply forceps in a case of labour D tells C he will expect a fee of a guinea. Is D justified in asking such a fee?* Is D justified in retaining it having first obtained consent, and who should pay? Should C pay or should his employer in case the patient does not do so? I am, Sirs yours faithfully

August 28th, 1902. JUSTITIA.

*** In our opinion D was quite justified in asking a fee but he should not retain it, for unless some special arrangement was made, all fees received by a locum tenent belong to the practitioner whose deputy he is. In the case of the patient not paying the fee C's employer will be legally liable, but of course the matter could be easily arranged by A and B when they return.—ED. L.

DETAILED MEDICAL ACCOUNTS.

To the Editors of THE LANCET

SIRS —Having had but a short experience of general practice I should like to know your opinion on the merits or otherwise of giving our patients a more or less detailed account when sending in our half *yearly or yearly bills The usual custom of merely stating the one* item of Attendance and medicine" does not to my mind appear quite satisfactory I should think the average business-like patient would prefer to have something a little more definite Nowadays we like to know what we are paying for and though the medical profession stands upon a different footing to all others yet I think there might be some alteration in the matter of our accounts which would be an improvement without reducing them to the level of ordinary trade bills which is to be avoided Of course there is difficulty at the outset as it does not seem desirable to me to enter every detail for which we charge, such as Bottle of medicine 2s 6d while if we do not do that, what is the next best course to pursue? I think we rather lay ourselves open to questioning on the part of our patients as to how such and such an account is made up and this might be avoided if we gave some indication of the services which we have rendered. Some such plan as stating the number of attendances per month and medicine for same might be resorted to or the figure due for each month without referring to the attendances or a combination of the two. I am afraid that this would mean a considerable increase in the trouble of preparing accounts but would not that be compensated by the satisfaction to our patients which would accrue from this more business-like procedure? One hesitates to adopt a new departure such as I have suggested without advice on the subject, and you, Sirs are in a position to afford such advice. Would the method I have here roughly sketched—or a similar one that your readers might suggest—be derogatory to the dignity of the profession?

I am, Sirs yours faithfully

Bept 2nd 1902. LEDGER

* The question of detailed medical accounts is a difficult one upon which to dogmatise. Perhaps some of our readers will give us their experiences.—ED L.

THE LAW FUND

THE following additional subscriptions have been received by Dr Paramore 2, Gordon-square W C:—Mr Clement Lucas £2 2s; Dr Ernest Alfred Edelsten 10s 6d.; Mr F R. Mallard 10s 6d.; Dr Prosser James £1 1s

THE CIRCULATION OF DISEASE.

To the Editors of THE LANCET

SIRS —Flies dust milk water &c are all credited with being vehicles for the spread of disease but what is more likely to carry infection and what is more circulated than money? If an ordinary penny could speak what a tale it might unfold! From the mouth of the old lady in an omnibus to the conductor's bag; from this to the trousers pocket of some labourer whose wife when he comes home gives it to the baby to play with Little Tootsie as is usual with babies sucks it and then little Annie just convalescent from scarlet fever gets hold of it. By-and by Annie goes to sleep and the penny rolls on to the floor where it may encounter some of Uncle Tom's phthisical expectoration Before long the penny is picked up from the floor and a jug (with the penny in it) is sent to the public-house for half a pint of ale (Who has not heard the story of the little girl who was sent to purchase three pennyworth of treacle and when the grocer having filled the jug with treacle asked her for the money she replied Please sir mother put the pennies in the jug"?) From the jug the penny is transferred to the till and is not long in coming into the possession of a child who may fall a victim to scarlet fever germs which had come from little Annie s hands I am sure that water in which old, greasy, thumbed £1 notes, American "greenbacks, and Indian rupee notes had been soaked would yield a host of noxious germs Isolation hospitals and sanitary precautions render valuable service in limiting the spread of disease but they are not enough, and I would suggest the formation of a society for the prevention of the circulation of disease whose business would be to consider all the different ways by which disease is spread There are few persons of sense who will not agree with my opinion that at all theatres banks, railway stations, and other places where large amounts of money are received there ought to be sterilisers into which all coins should be dropped In a practice I once had where I was accustomed to take a quantity of cash it was my custom to put all coins into a pot of water kept boiling over a small gas stove the coins being afterwards dried with a cloth In Uganda where the coinage consists of strings of cowrie shells, 900 to 1000 going to the rupee is it any wonder that small pox itch &c are so prevalent? It is a common sight to see a native with his fortune round his neck He may be covered with itch or have just got over small pox but it is all the same to him He goes to market and buys some bananas which cost him some shells these he hands over with the words ' Here you are, my friend unwittingly handing over germs of all sorts gratis

I am Sirs yours faithfully
Ralph Stoney
Medical Officer, Uganda Protectorate
Mbarara Ankole June 12th 1902

THE TREATMENT OF ASTHMA.

To the Editors of The Lancet

Sirs —Could you give me any information *re* Dr Tucker s atomizer for asthma? I know a lady who has been for many years a great sufferer from asthma and she tells me what a great benefit she has derived from this after stramonium &c. given in the ordinary way has had little or no good effect Therefore I would like to know what legitimate medicine can offer her, as I know nothing of this Dr Tucker but would greatly like a wrinkle as to this treatment

I am Sirs, yours faithfully
Sept 2nd 1902 Rusticus

*** We know nothing of the apparatus in question —Ed L

THE Y' FUND

Surgeon General H S Muir begs thankfully to acknowledge additional donations towards the above Fund from Mrs Hamilton Turner, Mr A. Haldinstein, Mrs A Halford Mr R Halford, Mrs Julius Meyer Mrs Edmund Davis Anonymous" (from several members of one family) Lieutenant Colonel O H. Channer I M S and the following officers of the Royal Army Medical Corps Lieutenant-Colonel J C Culling, Majors S R Wills, E Eckersley R. G Hanley Captain J G McNaught and Lieutenant F M Parry The fund now amounts to £582 As it is proposed to close it towards the end of the current month intending subscribers are requested kindly to forward their donations within the next three weeks Should any reader of The Lancet desire further particulars with a view to expressing *practical sympathy* a copy of the letter giving particulars of the case will be forwarded on application to Surgeon-General Muir, 26 Kensington-gardens terrace Hyde Park, London, W

A QUERY

To the Editors of The Lancet

Sirs —Does any medical man know anything of Dr Brillon of Paris and his ' cure" of masturbation? A patient suffering from the evil habit seeks reliable information before placing himself under treatment, ordinary remedies having failed

I am Sirs yours faithfully,
Sept 1st 1902 Enquirer.

MEDICAL EVIDENCE AT CORONERS INQUESTS

To the Editors of The Lancet

Sirs —I shall feel very grateful for your opinion or that of some of your numerous readers with regard to this case involving the question of a coroner s treatment of members of the profession in the witness box I will not go further into the case than to say that a healthy looking lad, aged nine years died suddenly on Tuesday, August 26th, at 9.30 P M after exhibiting symptoms which left considerable doubt in my mind as to the cause of death It seemed to me the case might be one either of cerebral lesion such as abscess with rupture hæmorrhage &c or of abdominal lesion—e g perforation—although pulse temperature and facial expression hardly warranted an expression of opinion in favour of the latter I asked the coroner through his officer whether he wished to hold an inquiry, hinting that I thought the case much too suddenly fatal for meningitis He sent me back a note saying that he understood I was 'satisfied the cause of death was meningitis" and asking if I was "satisfied the cause was natural" Now I was by no means satisfied as to the former statement had it been so I should not have troubled him at all as I had seen the boy twice the evening he died. Finally a post-mortem examination and inquest were ordered and it was when in the witness-box that I hold I was unfairly treated The coroner began to ask me a great many irrelevant questions In fact it was more a public examination in medicine and surgery than an inquest, and he even went so far as to ask why I had not examined the eyes ophthalmoscopically Of course, the idea of such a thing was absurd considering the boy's condition Then he wished to know why some one else was not called in in a way which left the impression on my mind and probably on the jury s that he attached little importance to my opinion Had I been an unqualified assistant or mere surgery help instead of a practitioner of some 15 years standing I could have had no less consideration at his hands As a matter of fact there was little time for a consultation and the parents were ordinary working people with, I presume, not too much ready money at hand. Then not having my thermometer (or rather having a broken one) on my first visit I did not take the temperature, and here was a splendid opportunity He referred to this *only* five times Mark you no one had ever hinted that my conduct of the case was in any way unsatisfactory Now, Sirs, has the profession just to bear this sort of thing without redress? I must say, in common fairness to coroners generally, it is unusual in my experience which is rather extensive for I was for some years locum tenent in many parts of England Of course, this sort of thing may be repeated in my case or some one else's. Must we grin and bear it? I ought to say a duodenal ulcer was found post mortem which had perforated

I am, Sirs yours faithfully,
Sept 2nd 1902. M.B Edin

THE HUMOURS OF CONSCIENTIOUS OBJECTION

The responsibility (if any) for the following rests with a Whitehav contemporary A ' conscientious objector who had been repeated refused an exemption certificate made a renewed application in th local court. He had in the meantime written to the Local Gover ment Board stating the facts from his point of view and he informe the bench of the nature of the communication "You may have conscientious objection to vaccination,' said one of the magistrate "but we have a conscientious objection to giving you a certificate "Yes,' quickly responded the applicant, but the law has not pr vided for your conscience" The magistrates were so impressed wit the cogency of this argument that they granted the exemptio certificate

A DANGEROUS EXHIBITION OF IRON

To the Editors of The Lancet

Sirs —The discovery by myself of acicular particles of iron in bres leads me to suggest that metal exhibited in such a form may *steel* march—perhaps a *dead* one—on the appendix of the genus homo

I am, Sirs yours faithfully,
L Grey Thompson, M.D Aberd.
Launceston, Tasmania, July 22nd, 1902

MEDICINE AS A CAREER

To the Editors of The Lancet

Sirs —I should be extremely grateful if you will favour me wit your opinion and advice in the following I have recently bought practice in a working-class town of about 10 000 inhabitant Directly opposite my surgery there is a cash chemist Now this ma does a tremendous business which consists chiefly in treating medic and surgical cases He not only dispenses his own medicines (whic he simply labels under his name, cough medicine rheumatic medicine &c) but holds consultations with people—the same people—for day and weeks In these consultations he examines people feels the pulse takes the temperature, and *in short, poses as doctor in every way* except name My patients have invariably gone through his hands first The custom here seems to be to visit a doctor only as a last resource. I have had several patients suffering from ambulatory typhoid and other fevers who have been under this chemist s care for a week or a fortnight before coming to me His surgical reputation is also well established. Only to-day a man came here suffering from tuberculous synovitis of the knee-joint. He has been under the chemist s treatment for a month whose treatment, the man informs me consisted of rubbing with different substances This treatment has been so detrimental that at last the man became alarmed and changed his surgeon. I cannot help feeling that such things should not be allowed in fairness both to the public and the medical profession There are two other medical men here but all our practices together are not equal to this consulting chemist s I am, Sirs yours faithfully,
August 28th 1902. Dubious.

*** There is at present no law in this country to prevent any one, however ignorant or incompetent from practising medicine or surgery provided that such person does not falsely pretend to be a registered person —Ed L

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* TO THE EDITORS, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18s. carriage extra.

Cases for binding the half year's numbers are now ready Cloth gilt lettered, price 2s, by post 2s 3d

To be obtained on application to the Manager accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions post free, either from THE LANCET Offices or from Agents are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank Westminster Branch") should be made payable to the Manager Mr CHARLES GOOD THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND LONDON ENGLAND

A Presidential Address

Delivered at the Meeting at Belfast, on Sept 10th 1902, of the British Association for the Advancement of Science

BY JAMES DEWAR, F.R.S., F.C.S.,

JACKSONIAN PROFESSOR OF EXPERIMENTAL PHILOSOPHY CAMBRIDGE UNIVERSITY; FULLERIAN PROFESSOR OF CHEMISTRY ROYAL INSTITUTION LONDON

PROFESSOR DEWAR commenced his address with an appropriate reference to King Edward's happy restoration to health. He then paid a sympathetic tribute to the memory of three members of the Association deceased since the last meeting—namely Mr George Griffith Sir Joseph Gilbert and Professor Alfred Cornu of Paris. In the next place he drew attention to the prominent position held by Belfast as one of the great cities of the United Kingdom and reviewed some points of the presidential address delivered by Professor Tyndall at the meeting of the Association in Belfast 28 years before. He then made some remarks on the endowment of education with especial reference (1) to the benefactions due to Mr. Cecil Rhodes and Mr Andrew Carnegie and (2) to the financial aspect of the work done at the Royal Institution in Albemarle-street, London. He had obtained from the books accurate statistics of the total expenditure on experimental inquiry and public demonstrations at the Royal Institution for 100 years—i.e for the whole of the nineteenth century—and he had found that the total outlay was £119 800 or an average of £1200 per annum, which was not a large sum considering that this period included the achievements of Young Davy Faraday and Tyndall. He then briefly discussed the causes of the rapid growth in Germany of trades and industries connected with chemistry after which he continued as follows —

HISTORY OF COLD AND THE ABSOLUTE ZERO

Science is advancing in so broad a front by the efforts of so great an army of workers that it would be idle to attempt within the limits of an address to the most indulgent of audiences anything like a survey of chemistry alone. But I have thought it might be instructive, and perhaps not uninteresting to trace briefly in broad outline the development of that branch of study with which my own labours have been recently more intimately connected—a study which I trust I am not too partial in thinking is as full of philosophical interest as of experimental difficulty The nature of heat and cold must have engaged thinking men from the very earliest dawn of speculation upon the external world but it will suffice for the present purpose if we take up the subject where it stood after the great revival of learning and as it was regarded by the father of the inductive method. That this was an especially attractive subject to Bacon is evident from the frequency with which he recurs to it in his different works, always with lamentation over the inadequacy of the means at disposal for obtaining a considerable degree of cold. Thus in the chapter in the Natural History Sylva Sylvarum, ' entitled Experiments in Consort touching the Production of Cold he says The production of cold is a thing very worthy of the inquisition both for the use and the disclosure of causes For heat and cold are nature's two hands whereby she chiefly worketh, and heat we have in readiness in respect of the fire, but for cold we must stay till it cometh or seek it in deep caves or high mountains and when all is done we cannot obtain it in any great degree, for furnaces of fire are far hotter than a summer sun but vaults and hills are not much colder than a winter's frost." The great Robert Boyle was the first experimentalist who followed up Bacon's suggestions. In 1682 Boyle read a paper to the Royal Society on New Experiments and Observations touching Cold or an Experimental History of Cold, published two years later in a separate work. This is really a most complete history of everything known about cold up to that date, but its great merit is the inclusion of numerous experiments made by Boyle himself on frigorific mixtures and the general effects of such upon matter The agency chiefly used by Boyle in the conduct of his experiments was the glaciating mixture of snow or ice and salt. In the course of his experiments he made many important observations. Thus he observed that the salts which did not help the snow or ice to dissolve faster gave no effective freezing and he showed that water in becoming ice expands by about one-ninth *of its volume and bursts gun barrels.* The greatest degree of cold that Boyle was able to produce did not make air exposed to its action lose a full tenth of its own volume, so that, in his own word the cold does not weaken the spring by anything near so considerable as one would expect." After making this remarkable observation and commenting upon its unexpected nature it is strange that he did not follow it up. After the masterly essay of Boyle the attention of investigators was chiefly directed to improving thermometrical instruments The old air thermometer of Galileo being inconvenient to use, the introduction of fluid thermometers greatly aided the inquiry into the action of heat and cold. For a time great difficulty was encountered in selecting proper fixed points on the scales of such instruments and this stimulated men like Huyghens, Newton, Hooke and Amontons to suggest remedies and to conduct experiments. By the beginning of the eighteenth century the freezing point and the boiling point of water were agreed upon as fixed points and the only apparent difficulties to be overcome were the selection of the fluid, accurate calibration of the capillary tube of the thermometer and a general understanding as to scale divisions It must be confessed that great confusion and inaccuracy in temperature observations arose from the variety and crudeness of the instruments. This led Amontons in 1702-03 to contribute two papers to the French Academy which reveal great originality in the handling of the subject and which, strange to say are not generally known. The first discourse deals with some new properties of the air and the mean of accurately ascertaining the temperature in any climate. He regarded heat as due to a movement of the particles of bodies though he did not in any way specify the nature of the motion involved and as the general cause of all terrestrial motion so that in its absence the earth would be without movement in its smallest parts. The new facts he records are observations on the spring or pressure of air brought about by the action of heat. He shows that different masses of air measured at the same initial spring or pressure, when heated to the boiling point of water acquire equal increments of spring or pressure, provided the volume of the gas be kept at its initial value. Further he proves that if the pressure of the gas before heating be doubled or tripled, then the additional spring or pressure resulting from heating to the boiling point of water is equally doubled or tripled In other words the ratio of the total spring of air at two definite and steady temperatures and at constant volume is a constant, independent of the mass or the initial pressure of the air in the thermometer These results led to the increased perfection of the air thermometer as a standard instrument, Amontons idea being to express the temperature at any locality in fractions of the degree of heat of boiling water The great novelty of the instrument is that temperature is defined by the measurement of the length of a column of mercury In passing he remarks that we do not know the extreme of heat and cold but that he has given the results of experiments which establish correspondences for those who wish to consider the subject. In the following year Amontons contributed to the Academy a further paper extending the scope of the inquiry He there pointed out more explicitly that as the degrees of heat in his thermometer are registered by the height of a column of mercury, which the heat is able to sustain by the spring of the air it follows that the extreme cold of the thermometer will be that which reduces the air to have no power of spring This, he says will be a much greater cold than what we call "very cold " because experiments have shown that if the spring of the air at boiling point is 73 inches the degree of heat which remains in the air when brought to the freezing point of water is still very great for it can still maintain the spring of 51½ inches The greatest climatic cold on the scale of units adopted by Amontons is marked 50 and the greatest summer heat 58. the value for boiling water being 73, and the zero being 52 units below the freezing point. Thus Amontons was the first to recognise that the use of air as a thermometric substance led to the inference of the existence of a zero of temperature, and his scale is nothing else than the absolute one we are now so familiar with. It results from Amontons experiments that the air would have no spring left if it were cooled below the freezing point of water to about two and a half times the temperature range which separates the boiling point and the freezing-point.

In other words, if we adopt the usual centennial difference between these two points of temperature as 100° then the zero of Amontons' air thermometer is *minus* 240° This is a remarkable approximation to our modern value for the same point of *minus* 273° It has to be confessed that Amontons' valuable contributions to knowledge met with that fate which has so often for a time overtaken the work of too advanced discoverers, in other words, it was simply ignored, or in any case not appreciated, by the scientific world either of that time or half a century later It is not till Lambert, in his work on "Pyrometrie," published in 1779, repeated Amontons' experiments and endorsed his results that we find any further reference to the absolute scale or the zero of temperature Lambert's observations were made with the greatest care and refinement and resulted in correcting the value of the zero of the air scale to *minus* 270° as compared with Amontons *minus* 240° Lambert points out that the degree of temperature which is equal to zero is what one may call absolute cold, and that at this temperature the volume of air would be practically nothing In other words the particles of the air would fall together and touch each other and become dense like water, and from this it may be inferred that the gaseous condition is caused by heat. Lambert says that Amontons' discoveries had found few adherents because they were too beautiful and advanced for the time in which he lived.

About this time a remarkable observation was made by Professor Braun at Moscow who, during the severe winter of 1759, succeeded in freezing mercury by the use of a mixture of snow and nitric acid. When we remember that mercury was regarded as quite a peculiar substance possessed of the essential quality of fluidity we can easily understand the universal interest created by the experiment of Braun This was accentuated by the observations he made on the temperature given by the mercury thermometer, which appeared to record a temperature as low as *minus* 200° C The experiments were soon repeated by Hutchins at Hudson's Bay who conducted his work with the aid of suggestions given him by Cavendish and Black. The result of the new observations was to show that the freezing point of mercury is only *minus* 40° C, the errors in former experiments having been due to the great contraction of the mercury in the thermometer in passing into the solid state From this it followed that the enormous natural and artificial colds which had generally been believed in had no proved existence Still, the possible existence of a zero of temperature very different from that deduced from gas thermometry had the support of such distinguished names as those of Laplace and Lavoisier In their great memoir on "Heat," after making what they consider reasonable hypotheses as to the relation between specific heat and total heat, they calculate values for the zero which range from 1500° to 3000° below melting ice On the whole, they regard the absolute zero as being in any case 600° below the freezing point. Lavoisier in his "Elements of Chemistry," published in 1792, goes further in the direction of indefinitely lowering the zero of temperature when he says "We are still very far from being able to produce the degree of absolute cold, or total deprivation of heat, being unacquainted with any degree of coldness which we cannot suppose capable of still further augmentation." Even as late as the beginning of the nineteenth century we find Dalton; in his "New System of Chemical Philosophy," giving 10 calculations of this value and adopting finally as the natural zero of temperature *minus* 3000° C

In Black's lectures we find that he takes a very cautious view with regard to the zero of temperature, but as usual is admirably clear with regard to its exposition. Thus he says 'We are ignorant of the lowest possible degree or beginning of heat Some ingenious attempts have been made to estimate what it may be, but they have not proved satisfactory Our knowledge of the degrees of heat may be compared to what we should have of a chain the two ends of which were hidden from us and the middle only exposed to our view We might put distinct marks on some of the links and number the rest according as they are nearest to, or further removed from, the principal links, but not knowing the distance of any links from the end of the chain we could not compare them together with respect to the distance or say that one link was twice as far from the end of the chain as another' It is interesting to observe, however, that Black was evidently well acquainted with the work of Amontons and strongly supports his inference as to the nature of air Thus, in discussing the general cause of vaporisation Black says that some philosophers have adopted the view "that every palpable elastic fluid in nature is produced and preserved in this form by the action of heat Mr Amontons, an ingenious member of the late Royal Academy of Sciences, at Paris, was the first who proposed this idea with respect to the atmosphere. He supposed that it might be deprived of the whole of its elasticity and condensed and even frozen into a solid matter, were it in our power to apply to it a sufficient cold, that it is a substance that differs from others by being incomparably more volatile, and which is therefore converted into vapour and preserved in that form by a weaker heat than any that ever happened or can obtain in this globe, and which, therefore, cannot appear under any other form than the one it now wears, so long as the constitution of the world remains the same or as at present" The views that Black attributes to Amontons have been generally associated with the name of Lavoisier who practically admitted similar possibilities as to the nature of air, but it is not likely that in such matters Black would commit any mistake as to the real author of a particular idea, especially in his own department of knowledge Black's own special contribution to low temperature studies was his explanation of the interaction of mixtures of ice with salts and acids by applying the doctrine of the latent heat of fluidity of ice to account for the frigorific effect In a similar way Black explained the origin of the cold produced in Cullen's remarkable experiment of the evaporation of ether under the receiver of an air pump by pointing out that the latent heat of evaporisation in this case necessitated such a result Thus, by applying his own discoveries of latent heat, Black gave an intelligent explanation of the cause of all the low temperature phenomena known in his day

After the gaseous laws had been definitely formulated by Gay-Lussac and Dalton the question of the absolute zero of temperature, as deduced from the properties of gases, was revised by Clement and Desormes These distinguished investigators presented a paper on the subject to the French Academy in 1812 which it appears was rejected by that body The authors subsequently elected to publish it in 1819 Relying on what we know now to have been a faulty hypothesis they deduced from observations on the heating of air rushing into a vacuum the temperature of *minus* 267° as that of the absolute zero After this time the zero of temperature was generally recognised as a fixed ideal point, but in order to show that it was hypothetical a distinction was drawn between the use of the expressions zero of absolute temperature and the absolute zero

The whole question took an entirely new form when Lord Kelvin, in 1848, after the mechanical equivalent of heat had been determined by Joule, drew attention to the great principles underlying Carnot's work on the "Motive Power of Heat," and applied them to an absolute method of temperature measurement, which is completely independent of the properties of any particular substance. The principle was that for a difference of one degree on this scale, between the temperatures of the source and refrigerator, a perfect engine should give the same amount of work in every part of the scale Taking the same fixed points as for the centigrade scale, and making 100 of the new degrees cover that range, it was found that the degrees not only within that range, but as far beyond as experimental data supplied the means of comparison, differed by only minute quantities from those of Regnault's air thermometer The zero of the new scale had to be determined by the consideration that when the refrigerator was at the zero of temperature the perfect engine should give an amount of work equal the full mechanical equivalent of the heat taken up T led to a zero of 273° below the temperature of freezing water, substantially the same as that deduced from a study of the gaseous state It was a great advance to demonstrate by the application of the laws of thermodynamics, not only that the zero of temperature is a reality, but that it must be located at 273° below the freezing-point of water As only one has attempted to impugn the solid foundation of theory and experiment on which Lord Kelvin based his thermodynamic scale the existence of a definite zero of temperature must be acknowledged as a fundamental scientific fact.

LIQUEFACTION OF GASES AND CONTINUITY OF STATE.

In these speculations, however chemists were dealing theoretically with temperatures to which they could not make any but the most distant experimental approach Davy and Faraday made the most of the means at command in liquefying the more condensable gases, but chemists were sorely hampered by the want of some powerful and accessible agent for the production of temperatures much lower than had ever been attained. That want was supplied by Thilorier who in 1835 produced liquid carbonic acid in large quantities and further made the fortunate discovery that the liquid could be frozen into a snow' by its own evaporation. Faraday was prompt to take advantage of this new and potent agent. *Under exhaustion he lowered its boiling point* from *minus* 78° C to *minus* 110° C, and by combining this low temperature with pressure all the gases were liquefied by the year 1844 with the exception of the three elementary gases—hydrogen, nitrogen and oxygen—and three compound gases—*carbonic oxide, marsh gas, and nitric oxide.* Andrews some 25 years after the work of Faraday attempted to induce change of state in the uncondensed gases' by using much higher pressures than Faraday employed. Combining the temperature of a solid carbonic acid bath with pressures of *300 atmospheres Andrews found that none of these gases* exhibited any appearance of liquefaction in such high states of condensation but so far as change of volume by high compression went Andrews confirmed the earlier work of Natterer by showing that the gases become proportionately less compressible with growing pressure. While such investigations were proceeding Regnault and Magnus had completed their refined investigations on the laws of Boyle and Gay Lussac. A very important series of experiments was made by Joule and Kelvin On the Thermal Effects of Fluids in Motion," about 1862, in which the thermometrical effects of passing gases under compression through porous plugs furnished important data for the study of the mutual action of the gas molecules No one, however, had attempted to make a complete study of a liquefiable gas throughout wide ranges of temperature. This was accomplished by Andrews in 1869 and his Bakerian Lecture On the Continuity of the Gaseous and Liquid States of Matter" will always be regarded as an epoch making investigation. During the course of this research Andrews observed that liquid carbonic acid raised to a temperature of *minus* 31° C lost the sharp concave surface of demarcation between the liquid and the gas, the space being now occupied by a homogeneous fluid which exhibited when the the pressure was suddenly diminished or the temperature slightly lowered a peculiar appearance of moving or flickering striæ, due to great local alterations of density At temperatures above *minus* 31° C. the separation into two distinct kinds of matter could not be effected even when the pressure reached 400 atmospheres. This limiting temperature of the change of state from gas to liquid Andrews called the critical temperature. He showed that this temperature is constant and differs with each substance and that it is always associated with a definite pressure peculiar to each body Thus the two constants critical temperature and pressure which have been of the greatest importance in subsequent investigations, came to be defined and a complete experimental proof was given that the gaseous and liquid states are only distinct stages of the same condition of matter and are capable of passing into one another by a process of continuous change.

In 1873 an essay ' On the Continuity of the Gaseous and Liquid State, full of new and suggestive ideas was published by van der Waals who recognising the value of Clausius's new conception of the virial in dynamics, for a long continued series of motions either oscillatory or changing exceedingly slowly with time applied it to the consideration of the molecular movements of the particles of the gaseous substance and after much refined investigation and the fullest experimental calculation available at the time devised his well known equation of continuity *Its paramount merit is that it is based entirely on a mechanical foundation and is in no sense empiric* we may therefore look upon it as having a secure foundation in fact, but as being capable of extension and improvement. James Thomson, realising that the straight-line breach of continuous curvature in the Andrews isothermals was untenable to the physical mind propounded his emendation of the Andrews curves—namely, that they were continuous and of S form. We also owe to James Thomson the conception and execution of a three-dimensional model of Andrews's results which has been of the greatest service in exhibiting the three variables by *means of a specific surface afterwards* greatly extended and developed by Professor Willard Gibbs. The suggestive work of James Thomson undoubtedly was a valuable aid to van der Waal. for as soon as he reached the point where his equation had to show the continuity of the two states this was the first difficulty he had to encounter and he succeeded in giving the explanation. He also gave a satisfactory reason for *the existence of a minimum* value of the product of volume and pressure in the Regnault isothermals. His isothermals with James Thomson's completion of them were now shown to be the results of the laws of dynamics. Andrews applied the new equation to *the consideration of the coefficients of expansion with temperature* and of pressure with temperature showing that although they were nearly equal nevertheless they were almost independent quantities. His investigation of the capillarity constant was masterly, and he added further to *our knowledge of the magnitudes of the molecules of gases* and of their mean free paths Following up the experiments of Joule and Kelvin, he showed how their cooling coefficients could be deduced and proved that they vanished at a temperature in each case which is a constant multiple *of the specific critical temperature* The equation of continuity developed by van der Waals involved the use *of three constants instead of one as in the old law of* Boyle and Charles the latter being only utilised to express the relation of temperature, pressure, and volume when the *gas is far removed from its point of liquefaction Of the two* new constants one represents the molecular pressure arising from the attraction between the molecules, the other four times the volume of the molecules Given these constants of a gas, van der Waals showed that his equation not only fitted into the general characters of the isothermals but also gave the values of the critical temperature, the critical pressure, and the critical volume. In the case of carbonic acid the theoretical results were found to be in remarkable agreement with the experimental values *of Andrews. This* gave chemists the means of ascertaining the critical constants, provided sufficiently accurate data derived from the study of a few properly distributed isothermals of the gaseous substance were available Such important data came into the possession of chemists when Amagat published his valuable paper on The Isothermals of Hydrogen Nitrogen Oxygen Ethylene, &c. in the year 1880 It now became possible to calculate the critical data with comparative accuracy for the so-called permanent gases oxygen and nitrogen, and this was done by Sarrau in 1882. In the meantime a great *impulse had been given to a further attack upon the so-called* permanent gases by the suggestive experiments made by Pictet and Cailletet. The static liquefaction of oxygen was effected by Wroblewski in 1883 and thereby the theoretical conclusions derived from van de Waals's equation were substantially confirmed The liquefaction of oxygen and air was achieved through the use of liquid ethylene as a cooling agent, which enabled a temperature of *minus* 140 degrees to be maintained by its steady evaporation in vacuo. From this time liquid oxygen and air came to be regarded as the potential cooling agents for future research commanding as they did a temperature of 200 degrees below melting ice. The theoretical *side of the question received* at the hands of van der Waals a second contribution which was even more important than his original essay, and that was his novel and ingenious development of what he calls The Theory of Corresponding States." He defined the corresponding states of two substances as those in which the ratios of the temperature, pressure and volume to the critical temperature pressure and volume respectively were the same for the two substances, and in corresponding states he showed that the three pairs of ratios all coincided. From this a series of remarkable propositions were developed some now some proving previous laws that were hitherto only empiric and *some completing* and correcting *faulty though approximate* laws As examples, he succeeded in calculating the boiling point of carbonic acid from observations on ether vapour proved Kopp's law of molecular volumes and showed that at corresponding temperatures the molecular latent heats of vaporisation are *proportional to the absolute critical* temperature and that under the same conditions the coefficients of liquid expansion are inversely proportional to the absolute critical temperature and that the coefficient of liquid compressibility are inversely proportional to the critical pressure. *It is, perhaps, not too much to say that as* a prolific source of knowledge in the department dealing with the continuity of state in matter it would be necessary to go back to Carnot's cycle to find a *proposition of greater* importance than the theory of van der Waals and his development *of the law of corresponding states.*

It will be apparent from what has just been said that thanks to the labours of Andrews, van der Waals, and others, theory had again far outrun experiment The problem now was not so much how to produce intense cold as how to save it when produced from being immediately levelled up by the relatively superheated surroundings. Ordinary non conducting packings were inadmissible because they are both cumbrous and opaque, while in working near the limits of our resources it is essential that the product should be visible and readily handled. It was while puzzling over this mechanical and manipulative difficulty in 1892 that it occurred to me that the principle of an arrangement used nearly 20 years before in some calorimetric experiments, which was based upon the work of Dulong and Petit on radiation, might be employed with advantage as well to protect cold substances from heat as hot ones from rapid cooling I therefore tried the effect of keeping liquefied gases in vessels having a double wall, the annular space between being very highly exhausted. Experiments showed that liquid air evaporated at only one fifth of the rate prevailing when it was placed in a similar unexhausted vessel, owing to the convective transference of heat by the gas particles being enormously reduced by the high vacuum *But in addition these vessels lend themselves* to an arrangement by which radiant heat can also be cut off It was found that when the inner walls were coated with a bright deposit of silver the influx of heat was diminished to one sixth the amount entering without the metallic coating The total effect of the high vacuum and the silvering is to reduce the in going heat to about 3 per cent The efficiency of such vessels depends upon getting as high a vacuum as possible, and cold is one of the best means of effecting the desired exhaustion All that is necessary is to fill completely the space that has to be exhausted with an easily condensable vapour and then to freeze it out in a receptacle attached to the primary vessel that can be sealed off. The advantage of this method is that no air pump is required, and that theoretically there is no limit to the degree of exhaustion that can be obtained. The action is rapid, provided liquid air is the cooling agent, and vapours like mercury, water, or benzol are employed. It is obvious that when we have to deal with such an exceptionally volatile liquid as hydrogen the vapour filling may be omitted because air itself is now an easily condensable vapour In other words, liquid hydrogen collected in such vessels with the annular space full of air immediately solidifies the air and thereby surrounds itself with a high vacuum. In the same way, when it shall be possible to collect a liquid boiling on the absolute scale at about five degrees, as compared with the 20° of hydrogen, then you might have the annular space filled with the latter gas to begin with, and yet get directly a very high vacuum, owing to the solidification of the hydrogen Many combinations of vacuum vessels can be arranged and the lower the temperature at which we have to operate the more useful they become Vessels of this kind are now in general use and in them liquid air has crossed the American continent Of the various forms that variety is of special importance which has a spiral tube joining the bottom part of the walls, so that any liquid gas may be drawn off from the interior of such a vessel. In the working of regenerative coils such a device becomes all-important and such special vessels cannot be dispensed with for the liquefaction of hydrogen.

In the early experiments of Pictet and Cailletet cooling was produced by the sudden expansion of the highly compressed gas preferably at a low temperature, the former using a jet that lasted for some time, the latter an instantaneous adiabatic expansion in a strong glass tube Neither process was practicable as a mode of producing liquid gases but both gave valuable indications of partial change into the liquid state by the production of a temporary mist Linde, however, saw that the continuous use of a jet of highly compressed gas, combined with regenerative cooling must lead to liquefaction on account of what is called the Kelvin-Joule effect, and he succeeded in making a machine based on this principle, capable of producing liquid air for industrial purposes These experimenters had proved that, owing to molecular attraction, compressed gases passing through a porous plug or small aperture were lowered in temperature by an amount depending on the difference of pressure and inversely as the square of the absolute temperature. This means that for a steady difference of pressure the cooling is greater the lower the temperature. The only gas that did not show cooling under such conditions was hydrogen Instead of being cooled it became actually hotter The reason for this apparent anomaly in the Kelvin Joule effect is that every gas has a thermometric point of inversion above which it is heated and below which it is cooled. This inversion point, according to van der Waals, is six and three-quarter times the critical point. The efficiency of the Linde process depends on working with highly compressed gas well below the inversion temperature, and in this respect this point may be said to take the place of the critical one when in the ordinary way direct liquefaction is being effected by the use of specific liquid cooling agents The success of both processes depends upon working within a certain temperature range, only the Linde method gives us a much wider range of temperature within which liquefaction can be effected This is not the case if, instead of depending on getting cooling by the internal work done by the attraction of the gas molecules, we force the compressed gas to do external work as in the well known air machines of Kirk and Coleman. Both these inventors have pointed out that there is no limit of temperature, short of liquefaction of the gas in use in the circuit, that such machines are not capable of giving While it is theoretically clear that such machines ought to be capable of maintaining the lowest temperatures, and that with the least expenditure of power, it is a very different matter to overcome the practical difficulties of working such machines under the conditions. Coleman kept a machine delivering air at *minus* 83° for hours, but he did not carry his experiments any further Recently M. Claude of Paris has, however, succeeded in working a machine of this type so efficiently that he has managed to produce one litre of liquid air per horse-power expended per hour in the running of the engine. This output is twice as good as that given by the Linde machine and there is no reason to doubt that the yield will be still further improved It is clear, therefore, that in the immediate future the production of liquid air and hydrogen will be effected most economically by the use of machines producing cold by the expenditure of mechanical work.

LIQUID HYDROGEN AND HELIUM

Hydrogen is an element of especial interest, because the study of its properties and chemical relations led great chemists like Faraday, Dumas, Daniell, Graham, and Andrews to entertain the view that if it could ever be brought into the state of liquid or solid it would reveal metallic characters Looking to the special chemical relations of the combined hydrogen in water, alkaline oxides, acids, and salts, together with the behaviour of these substances on electrolysis, we are forced to conclude that hydrogen behaves as the analogue of a metal. After the beautiful discovery of Graham that palladium can absorb some hundreds of times its own volume of hydrogen and still retain its lustre and general metallic character the impression that hydrogen was probably a member of the metallic group became very general The only chemist who adopted another view was my distinguished predecessor Professor Odling In his "Manual of Chemistry," published in 1861, he pointed out that hydrogen has chlorous as well as basic relations, and that they are as decided important, and frequent as its other relations From such considerations he arrived at the conclusion that hydrogen is essentially a neutral or intermediate body and therefore we should not expect to find liquid or solid hydrogen possess the appearance of a metal This extraordinary prevision, so characteristic of Odling, was proved to be correct some 37 years after it was made Another curious anticipation was made by Dumas in a letter addressed to Pictet, in which he says that the metal most analogous to hydrogen is magnesium and that probably both elements have the same atomic volume, so that the density of hydrogen, for this reason, would be about the value elicited by subsequent experiments Later, in 1872 when Newlands began to arrange the elements in periodic groups, he regarded hydrogen as the lowest member of the chlorine family, but Mendéleef in his later classification placed hydrogen in the group of the alkaline metals, on the other hand Dr Johnstone Stoney classes hydrogen with the alkaline earth metals and magnesium. From this speculative divergency it is clear that no definite conclusion could be reached regarding the physical properties of liquid or solid hydrogen, and that the only way to arrive at the truth was to prosecute low temperature research until success attended the efforts to produce its liquefaction This result I definitely obtained in 1898 The case of liquid hydrogen is, in fact an excellent illustration of the truth already referred to, that no theoretical forecast however apparently justified by analogy can be finally accepted as true until confirmed by actual experiment. Liquid hydrogen is a colourless transparent body of extraordinary intrinsic interest. It has a clearly-defined surface, is easily seen, drops well, in spite of the fact that its surface tension is only the thirty fifth part of that of water or about one fifth that of liquid air and it can be poured easily from vessel to vessel. The liquid does not conduct electricity and if anything is slightly diamagnetic Compared with an equal volume of liquid air, it requires only one-fifth the quantity of heat for vaporisation, on the other hand its specific heat *is ten times that of liquid air or five times* that of water The coefficient of expansion of the fluid is remarkable, being about *ten times that of gas It is by far* the lightest liquid known to exist its density being only one-fourteenth that of water the lightest liquid previously known was liquid marsh gas, which is six times heavier The only solid which has so small density as to float upon its surface is a piece of pith wood. It is by far the coldest liquid known At ordinary atmospheric pressure it boils at *minus* 252 5° or 20 5° absolute. The critical point of the liquid is about 29° absolute, and the critical pressure not more than 15 atmospheres. The vapour of the hydrogen arising from the liquid has nearly the density of air—that is, it is 14 times that of the gas at the ordinary temperature. Reduction of the pressure by an air pump brings down the temperature to *minus* 258° when the liquid becomes a solid resembling frozen foam and this by further exhaustion is cooled to *minus* 260° or 13° absolute, which is the lowest steady temperature that has been reached. *The solid may also be got in the form of* a clear transparent ice melting at about 15° absolute, under a pressure of 55 millimetres possessing the unique density of one-eleventh that of water Such cold involves the solidification of every gaseous substance but one that is at present definitely known to the chemist and so liquid hydrogen introduces the investigator to a world of solid bodies. The contrast between this refrigerating substance and liquid air is most remarkable. On the removal of the loose plug of cotton wool used to cover the mouth of the vacuum vessel in which it is stored the action is followed by a miniature snowstorm of solid air formed by the freezing of the atmosphere at the point where it comes into contact with the cold vapour rising from the liquid. This solid air falls into the vessel and accumulates as a white snow at the bottom of the liquid hydrogen. When the outside of an ordinary test tube is cooled by immersion in the liquid it is soon observed to fill up with solid air and if the tube be now lifted out a double effect is visible, for liquid air is produced both in the inside and on the outside of the tube—in the one case by the melting of the solid and in the other by condensation from the atmosphere A tuft of cotton-wool soaked in the liquid and then held near the pole of a strong magnet is attracted and it might be inferred therefrom that liquid hydrogen is a magnetic body This however is not the case the attraction is due neither to the cotton wool nor to the hydrogen—which indeed, evaporates almost as soon as the tuft is taken out of the liquid—but to the oxygen of the air which is well known to be a magnetic body frozen in the wool by the extreme cold

The strong condensing powers of liquid hydrogen afford a simple means of producing vacua of very high tenuity When one end of a sealed tube containing ordinary air is placed for a short time in the liquid the contained air accumulates as a solid at the bottom while the higher part is almost entirely deprived of particles of gas. So perfect is the vacuum thus formed that the electric discharge can be made to pass only with the greatest difficulty Another important application of liquid air liquid hydrogen &c. is as analytic agents. Thus, if a gaseous mixture be cooled by means of liquid oxygen only those constituents will be left in the gaseous state which are less condensable than oxygen Similarly if this gaseous residue be in its turn cooled in liquid hydrogen a still further separation will be effected, everything that is less volatile than hydrogen being condensed to a liquid or solid. By proceeding in this fashion it has been found possible to isolate helium from a mixture in which it is present to the extent of only one part in 1000 By the evaporation of solid hydrogen under the air pump we can reach within 13° or 14° of the zero but there or thereabouts our progress is barred. This gap of 13° might seem at first sight insignificant in comparison with the hundreds that have already been conquered. But to win one degree low down the scale is quite a different matter from doing so at higher temperatures in fact, to annihilate these few remaining degrees would be a far greater achievement than any so far accomplished in low temperature research. That the zero will ever be reached by man is extremely improbable. But supposing the experimenter to be able to reach within a few degrees of the zero it is by no means certain that he would find the near approach of the death of matter sometimes pictured. Any forecast of the phenomena that would be seen must be based on the assumption that there is continuity between the processes studied at attainable temperatures and those which take *place at still lower ones. But it would be rash to take for* granted that the changes which have been traced in explored *regions continue to the same extent and in the same direction* in those which are as yet unexplored for evidence to a contrary effect has already been obtained in at least one case A series of experiments with pure metals showed that their electrical resistance gradually decreases as they are cooled to lower and lower temperatures in such ratio that it appeared probable that at the zero of absolute temperature they would have no resistance at all and would become perfect conductors of electricity This was the inference that seemed justifiable by observations taken at depths of cold which can be obtained by means of liquid air and less powerful refrigerants. But with the advent of the more powerful refrigerant liquid hydrogen it became necessary to revise that conclusion. A discrepancy was first observed when a platinum resistance thermometer was used to ascertain the temperature of that liquid boiling under atmospheric and reduced pressure. All known liquids, when *forced to evaporate* quickly by being placed in the exhausted receiver of an air pump undergo a reduction in temperature, but when hydrogen was treated in this way it appeared to be an exception. The resistance thermometer showed no such reduction as was expected and it became a question whether it was the hydrogen or the thermometer that was behaving abnormally Ultimately by the adoption of other thermometrical appliances, the temperature of the hydrogen was proved to be lowered by exhaustion as theory indicated Hence, it was the platinum thermometer which had broken down in other words the electrical resistance of the metal employed in its construction was not, at temperatures about *minus* 250° C. decreased by cold in the same proportion as at temperatures about *minus* 200° This being the case, there is no longer any reason to suppose that at the absolute zero platinum would become a perfect conductor of electricity and in view of the similarity between the behaviour of platinum and that of other pure metals in respect of temperature and conductivity the presumption is that the same is true of them also. It may safely be predicted that liquid hydrogen will be the means by which many obscure problems of physics and chemistry will ultimately be solved so that the liquefaction of the last of the old permanent gases is as pregnant now with future consequences of great scientific moment as was the liquefaction of chlorine in the early years of the last century

The next step towards the absolute zero is to find another gas more volatile than hydrogen and that we possess in the gas occurring in clevite identified by Ramsay as helium, a gas which is widely distributed like hydrogen in the sun, stars and nebulæ A specimen of this gas was subjected by Olszewski to liquid air temperatures combined with compression and subsequent expansion, following the Cailletet method, and resulted in his being unable to discover any appearance of liquefaction even in the form of mist. His experiments led *him to infer* that the boiling point of the substance is probably below nine degrees absolute. After Lord Rayleigh had found a new source of helium in the gases which are derived from the Bath springs and liquid hydrogen became available as a cooling agent a specimen of helium cooled in liquid hydrogen showed the formation of fluid but this turned out to be owing to the presence of an unknown admixture of other gases As a matter of fact a year before the date of this experiment I had recorded indications of the presence of unknown gases in the spectrum of helium derived from this source When subsequently such condensable constituents were removed the purified helium showed no signs of liquefaction even when compressed to 80 atmospheres while the tube containing it was surrounded with solid hydrogen. Further on suddenly expanding no instantaneous mist appeared. Thus helium was definitely proved to be a much more volatile substance than hydrogen in either the liquid or solid condition. The inference to be drawn from the adiabatic expansion effected under the circumstances is that helium must have touched a temperature of from 9° to 10° for a short time without showing any signs of liquefaction and consequently that the critical point must be still lower This would force us to anticipate that the boiling-point of the liquid will be about five degrees absolute, or liquid helium will be four times more volatile than liquid hydrogen, just as liquid hydrogen is four times more volatile than liquid air Although the liquefaction of the gas is a problem for the future this does not prevent us from safely anticipating some of the properties of the fluid body It would be twice as dense as liquid hydrogen with a critical pressure of only four or five atmospheres The liquid would possess a very feeble surface tension and its compressibility and expansibility would be about four times that of liquid hydrogen, while the heat required to vapourise the molecule would be about one fourth that of liquid hydrogen. Heating the liquid one degree above its boiling point would raise the pressure by one and three quarter atmospheres, which is more than four times the increment for liquid hydrogen. The liquid would be only 17 times denser than its vapour, whereas liquid hydrogen is 65 times denser than the gas it gives off Only some three or four degrees would separate the critical temperature from the boiling point and the melting point, whereas in liquid hydrogen the separation is respectively 10° and 15° As the liquid refractivities for oxygen, nitrogen, and hydrogen are closely proportional to the gaseous values, and as Lord Rayleigh has shown that helium has only one fourth the refractivity of hydrogen, although it is twice as dense, we must infer that the refractivity of liquid helium would also be about one-fourth that of liquid hydrogen. Now, hydrogen has the smallest refractivity of any known liquid, and yet liquid helium will have only about one-fourth of this value—comparable, in fact, with liquid hydrogen just below its critical point This means that the liquid will be quite exceptional in its optical properties and very difficult to see This may be the explanation of why no mist has been seen on its adiabatic expansion from the lowest temperatures Taking all these remarkable properties of the liquid into consideration one is afraid to predict that we are at present able to cope with the difficulties involved in its production and collection

THE UPPER AIR AND AURORAS

If a sample of liquid air cooled to the low temperature that can be reached by its own evaporation be connected by a pipe to a condenser cooled in liquid hydrogen then any volatile gases present in solution but less condensable than the chief constituents of the atmosphere will distil over with the first portions of the air, and can be pumped off, being uncondensable at the temperature of the condenser In this way a gas mixture containing of the known gases free hydrogen, helium, and neon has been separated from liquid air The total uncondensable gas separated in this way amounts to about one fifty thousandth of the volume of the air That free hydrogen exists in air in small amount is conclusively proved, but the actual proportion found by the process is very much smaller than Gautier has estimated by the combustion method The recent experiments of Lord Rayleigh show that Gautier, who estimated the hydrogen present as one five thousandth, has in some way produced more hydrogen than he can manage to extract from pure air by a repetition of the same process The spectroscopic examination of these gases throws new light upon the question of the aurora and the nature of the upper air On passing electric discharges through the tubes containing the most volatile of the atmospheric gases they glow with a bright orange light, which is especially marked at the negative pole. The spectroscope shows that this light consists, in the visible part of the spectrum, chiefly of a succession of strong rays in the red, orange, and yellow, attributed to hydrogen, helium, and neon. Besides these, a vast number of rays, generally less brilliant, are distributed through the whole length of the visible spectrum The greater part of these rays are of, as yet, unknown origin The violet and ultra violet part of the spectrum rivals in strength that of the red and yellow rays. As these gases probably include some of the gases that pervade inter planetary space, search was made for the prominent nebular, coronal, and auroral lines. No definite lines agreeing with the nebular spectrum could be found, but many lines occurred closely coincident with the coronal and auroral spectrum. But before discussing the spectroscopic problem it will be necessary to consider the nature and condition of the upper air

According to the old law of Dalton, supported by the modern dynamical theory of gases, each constituent of the atmosphere while acted upon by the force of gravity forms a separate atmosphere, completely independent, except as to temperature, of the others, and the relations between the common temperature and the pressure and altitude for each specific atmosphere can be definitely expressed If we assume the altitude and temperature known then the pressure can be ascertained for the same height in the case of each of the gaseous constituents, and in this way the percentage composition of the atmosphere at that place may be deduced. Suppose we start with a surface atmosphere having the composition of our air, only containing two ten thousandths of hydrogen, then at 37 miles, if a sample could be procured for analysis, we believe that it would be found to contain 12 per cent. of hydrogen and only 10 per cent. of oxygen The carbonic acid practically disappears, and by the time we reach 47 miles, where the temperature is *minus* 132°, assuming a gradient of 3·2° per mile, the nitrogen and oxygen have so thinned out that the only constituent of the upper air which is left is hydrogen If the gradient of temperature were doubled the elimination of the nitrogen and oxygen would take place by the time 37 miles was reached with a temperature of *minus* 220° The permanence of the composition of the air at the highest helium altitudes, as deduced from the basis of the dynamical theory of gases, has been discussed by Stoney, Bryan, and others It would appear that there is a consensus of opinion that the rate at which gases like hydrogen and helium could escape from the earth's atmosphere would be excessively slow Considering that to compensate any such loss the same gases are being supplied by actions taking place in the crust of the earth, we may safely regard them as necessarily permanent constituents of the upper air The temperature at the elevations we have been discussing would not be sufficient to cause any liquefaction of the nitrogen and oxygen, the pressure being so low If we assume the mean temperature as about the boiling point of oxygen at atmospheric pressure then a considerable amount of the carbonic acid must solidify as a mist if the air from a lower level be cooled to this temperature, and the same result might take place with other gases of relatively small volatility which occur in air This would explain the clouds that have been seen at an elevation of 50 miles, without assuming the possibility of water vapour being carried up so high The temperature of the upper air must be above that on the vapour pressure curve corresponding to the barometric pressure at the locality, otherwise liquid condensation must take place In other words, the temperature must be above the dew-point of air at that place At higher elevations, on any reasonable assumption of temperature distribution, we inevitably reach a temperature where the air would condense, just as Fourier and Poisson supposed it would, unless the temperature is arrested in some way from approaching the zero Both ultra-violet absorption and the prevalence of electric storms may have something to do with the maintenance of a higher mean temperature The whole mass of the air above 40 miles is not more than one seven hundredth part of the total mass of the atmosphere, so that any rain or snow of liquid or solid air, if it did occur, would necessarily be of a very tenuous description. In any case the dense gases tend to accumulate in the lower strata and the lighter ones to predominate at the higher altitudes, always assuming that a steady state of equilibrium has been reached. It must be observed, however, that a sample of air taken at an elevation of nine miles has shown no difference in composition from that at the ground, whereas, according to our hypothesis the oxygen ought to have been diminished to 17 per cent. and the carbonic acid should also have become much less This can only be explained by assuming that a large intermixture of different layers of the atmosphere is still taking place at this elevation This is confirmed by a study of the motions of clouds about six miles high which reveals an average velocity of the air currents of some 70 miles an hour; such violent winds must be the means of causing the intermingling of different atmospheric strata. Some clouds, however, during hot and thundery weather, have been seen to reach an elevation of 17 miles, so that we have direct proof that on occasion the lower layers of atmosphere are carried to a great elevation. The existence of an atmosphere at more than 100 miles above the surface of the earth is revealed to us by the appearance of meteors and fireballs, and when we can take photographs of the spectrum of such apparitions we shall learn a great deal about the composition of the upper air In the meantime Pickering's solitary spectrum of a meteor reveals an atmosphere of hydrogen and helium and so far this is corroborative of the doctrine which we have been discussing It has long been recognised that the aurora is the result of electric discharges within the limits of the earth's atmosphere, but it was difficult to understand why its spectrum should be so entirely different from anything which could be produced artificially by electric discharges through rarified air at the surface of the earth Writing in 1879 Rand Capron after collecting all the recorded observations, was able to enumerate no more than nine auroral rays, of which but one could with any probability be identified with rays emitted by atmospheric air under an electric discharge. But since that time observations of the spectra of auroras have been greatly multiplied chiefly through the Swedish and Danish Polar Expeditions and the length of spectrum recorded on the ultra violet side has been greatly extended by the use of photography so that in a recent discussion of the results, M Henri Stassano is able to enumerate upwards of 100 auroral rays of which the wave length *is more or less approximately known some* of them far in the ultra violet. Of this large number of rays he is able to identify within the probable limits of errors of observation about two-thirds as rays which Professor Liveing and myself have observed to be emitted by the most volatile gases of atmospheric air unliquefiable at the temperature of liquid hydrogen. Most of the remainder he ascribes to argon and some he might, with more probability have identified with krypton or xenon rays if he had been aware of the publication of wave lengths of the spectra of those gases and the identification of one of the highest rays of krypton with that most characteristic of auroras. The rosy tint often seen in auroras particularly in the streamers appears to be due mainly to neon of which the spectrum is remarkably rich in red and orange rays. The predominance of neon is not surprising seeing that from its relatively greater proportion in air and its low density it must tend to concentrate at higher elevations

[Professor Dewar here discussed the spectroscopic phenomena of auroras at some length and explained the theory of Arrhenius accounting for the electric discharges which are generally believed to occasion them. He then continued]

VARIOUS LOW TEMPERATURE RESEARCHES.

We may now summarise some of the results which have already been attained by low temperature studies. In the first place the great majority of chemical interactions are entirely suspended, but an element of such exceptional powers of combination as fluorine is still active at the temperature of liquid air Whether solid fluorine and liquid hydrogen would interact no one can at present say Bodies naturally become denser but even a highly expansive substance like ice does not appear to reach the density of water at the lowest temperature. This is confirmatory of the view that the particles of matter under such conditions are not packed in the closest possible way The force of cohesion is greatly increased at low temperatures as is shown by the additional stress required to rupture metallic wires. This fact is of interest in connexion with two conflicting theories of matter Lord Kelvin's view is that the forces that hold together the particles of bodies may be accounted for without assuming any other agency than gravitation or any other law than the Newtonian An opposite view is that the phenomena of the aggregation of molecules depend upon the molecular vibration as a physical cause. Hence, at the zero of absolute temperature, this vibrating energy being in complete abeyance, the phenomena of cohesion should cease to exist, and matter generally should be reduced to an incoherent heap of cosmic dust. This second view receives no support from experiment.

The photographic action of light is diminished at the temperature of liquid air to about 20 per cent. of its ordinary efficiency and at the still lower temperature of liquid hydrogen only about 10 per cent. of the original sensitivity remains At the temperature of liquid air or liquid hydrogen a large range of organic bodies and many inorganic ones acquire under exposure to violet light the property of phosphorescence Such bodies glow faintly so long as they are kept cold but become exceedingly brilliant during the period when the temperature is rising Even solid air is a phosphorescent body All the alkaline earth sulphides which phosphoresce brilliantly at the ordinary temperature lose this property when cooled, to be revived on heating, but such bodies in the first instance may be stimulated through the absorption of light at the lowest temperatures. Radio-active bodies, on the other hand like radium which are naturally self luminous, maintain this luminosity unimpaired at the very lowest temperature and are still capable of inducing phosphorescence in bodies like the platino-cyanides. Some crystals become for a time self luminous when cooled in liquid air or hydrogen, owing to the induced electric stimulation causing discharges between the crystal molecules. This phenomenon is very pronounced with nitrate of uranium and some platino-cyanides

[Professor Dewar here gave a concise *résumé* of the results of a long series of experiments made in conjunction with Professor Fleming, on the electric and magnetic properties of bodies at low temperatures. The subjects that had been under investigation might be classified as follows The Thermo-Electric Powers of Pure Metals the Magnetic Properties of Iron and Steel Dielectric Constants, the Magnetic and Electric Constants of Liquid Oxygen and Magnetic Susceptibility He then continued]

The effect of cold upon the life of living organisms is a *matter of great intrinsic interest as well as of wide theoretical* importance. Experiment indicates that moderately high temperatures are much more fatal at least to the lower forms of life, than are exceedingly low ones. Professor McKendrick froze for an hour at a temperature of *minus* 182° C samples of meat, milk &c. in sealed tubes when these were opened after being kept at blood heat for a few days their contents were found to be quite putrid. More recently some more elaborate tests were carried out at the Jenner Institute of Preventive Medicine on a *series of typical bacteria.* These were exposed to the temperature of liquid air for 20 hours, but their vitality was not affected, their functional activities remained unimpaired and the cultures which they yielded were normal in every respect. The same result was obtained when liquid hydrogen was substituted for air A similar persistence of life in seeds has been demonstrated even at the lowest temperature they were frozen for over 100 hours in liquid air at the instance of Messrs. Brown and Escombe, with no other result than to affect their protoplasm with a certain inertness, from which it recovered with warmth. Subsequently commercial samples of barley pea, vegetable marrow and mustard seeds were literally steeped for six hours in liquid hydrogen at the Royal Institution yet when they were sown by Sir W T Thiselton Dyer at Kew in the ordinary way the proportion in which germination occurred was no less than in the other batches of the same seeds which had suffered no abnormal treatment. Bacteria are minute vegetable cells which it has been found possible completely to triturate when the operation is carried out at the temperature of liquid air the cells then being frozen into hard breakable masses. The typhoid organism has been treated in this way and the cell plasma obtained for the purpose of studying its toxic and immunising properties It would hardly have been anticipated that liquid air should find such immediate application in biological research A research by Professor Macfadyen, just concluded has shown that many varieties of micro-organisms can be exposed to the temperature of liquid air for a period of six months without any appreciable loss of vitality although at such a temperature the ordinary chemical processes of the cell must cease. At such a temperature the cells cannot be said to be either alive or dead in the ordinary acceptation of these words. It is a new and hitherto unobtained condition of living matter—a third state A final instance of the application of the above methods may be given Certain species of bacteria during the course of their vital processes are capable of emitting light. If however the cells be broken up at the temperature of liquid air and the crushed contents brought to the ordinary temperature the luminosity function is found to have disappeared. This points to the luminosity not being due to the action of a ferment—a Luciferase"—but as being essentially bound up with the vital processes of the cells and dependent for its production on the intact organisation of the cell These attempts to study by frigorific methods the physiology of the cell have already yielded valuable and encouraging results and it is to be hoped that this line of investigation will continue to be vigorously prosecuted at the Jenner Institute

And now, in conclusion, I may remind you that I commenced by referring to the plaint of Elizabethan science, that cold was not a natural available product. In the course of a long struggle with nature man, by the application of intelligent and steady industry, has acquired a control over this agency which enables him to produce it at will and with almost any degree of intensity short of a limit defined by the very nature of things But the success in working what appears at first sight to be a quarry of research that would soon suffer exhaustion has only brought him to the threshold of new labyrinths The battle fields of science are the centres of a perpetual warfare in which there is no hope of final victory, although partial conquest is ever triumphantly encouraging the continuance of the disciplined and strenuous attack on the seemingly impregnable fortress of nature.

TETANUS AND VACCINATION

AN ANALYTICAL STUDY OF 95 CASES OF THE COMPLICATION

BY JOSEPH McFARLAND, M D ,
PROFESSOR OF PATHOLOGY AND BACTERIOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA

DURING the year 1901 an unusual number of cases of small pox in different parts of the United States stimulated the health authorities to a vigorous endeavour to protect the public by vaccination and in that year great activity in this direction took place throughout the United States

The occurrence of a number of cases of tetanus succeeding vaccination at first in Cleveland, Ohio, and then in Camden, New Jersey, early attracted my attention as this, to me, unknown complication seemed a matter of the greatest importance, increasing the danger of vaccination and correspondingly increasing the animosity of those misguided persons who have banded themselves together for the organised opposition of this well recognised and only safeguard against small pox.

The cases of tetanus in Camden have been so exploited in the newspapers and have been made the subject of so many editorial articles and comments in the medical press that they will, no doubt, form the starting-point of numerous future attacks against vaccination, so that I deemed it important that as many cases of the complication as could possibly be collected should be brought together and carefully analysed in order to determine whether tetanus is a necessary or an avoidable complication of vaccination If necessary, we should be prepared for it and should know how often to expect it, if avoidable, we should seek to eliminate it by every precaution regarding the selection of a superior virus and the performance of a careful operation. At all events, we should know what relationship exists between the two affections

TETANUS IS NOT A RECOGNISED COMPLICATION OF VACCINATION

The only text-book in which I have been able to find any mention made of the complication is the recent edition of Osler's "Text-book of Medicine" in which it is simply stated that "tetanus occasionally follows vaccination." In the Minority report of the British Commission, published in 1896, in which the disadvantages of vaccination are carefully and forcibly summarised, a single case, apparently the only one they were able to collect, is mentioned. Ordinary writers upon vaccination entirely ignore tetanus The literature on the subject is extremely meagre In the Index Catalogue of the Surgeon General's Library at Washington only *seven* cases are mentioned under titles by which they can be recognised and I have found a total of but 14 cases in the literature. These cases have occurred at remote periods in different parts of the world and were all attributed to secondary infection of the wound. It seems reasonable, therefore, to conclude that tetanus has not been a frequent or important complication of vaccination in the past, either in this or any other country It may however, be surmised that what is true at the present time has also been true in the past and that when a case of tetanus did occur an attempt was made to suppress rather than to publish it lest its influence should be injurious , but if in the past any such epidemics of tetanus had taken place as have been recently experienced the medical literature would certainly contain some reference to it, for, suppressed as the cases are at the present time, very few of the recent cases having been published in detail, rumours of cases and editorial articles referring to the cases and speculating upon their occurrence are to be found in many of the journals both in this country and abroad The lack of information concerning the complication cannot depend upon the failure to recognise it, as tetanus has been a well known disease for centuries and, indeed, very little has been added to its symptomatology since the days of Hippocrates

I have been able to collect a total of 95 cases of tetanus following vaccination Throughout the paper I shall refer to "cases," meaning by the term occurrences of tetanus that I have succeeded in authenticating and of which I have considerable detail, while the term "rumour" will be used for cases of tetanus the occurrence of which is certain but concerning which for various reasons I have been unable to secure the details The greater part of my information has been collected by personal corresponden and has been obtained with the request that it should l regarded as confidential I do not, therefore, append th synoptical lists from which my conclusions are drawn, though I can at once place the matter at the disposal of anyone interested in the subject

Cases of tetanus following vaccination are reported as follows —

1854 —Isabella XX. Dr J D Cottman, *New Orleans Medical and Surgical Journal*, 1854-55, vol xi , p 783

1878 —Edward K. Dr G Ross, *South Clinic*, Richmond, Va., 1878-79, vol. i p 468

1882.—Ben Jones Dr W C T Bates Transactions of the South Carolina Medical Association, Charleston 1882, vol xxxii p 105 —John McLane Dr T Dimon *St. Louis Courier of Medicine* 1882 vol vii, p 310-312.—D M Dr H J Berkeley, *Maryland Medical Journal* Baltimore 1882-1883 vol ix pp 241-245

1886 —Malo Dr Rudesindo Garcia Rijo *Cron Med Quir de la Habana*, 1886, vol xii p 388

1889 —Infant Bromley Case THE LANCET, Nov 2nd (p 922) and 9th (p 970), 1889

1891 —Negro boy Dr Ruiz *Cron Med Quir de la Habana* 1891 vol xvii p 649

1893 —M D W Bellport L I Dr S W S Toms *Medical News*, Feb 24th 1894

1897 —British Commission case Appendix IX to the Final Report of the Royal Commission on Vaccination 1897, Case 10 p 6

1899 —A K. XXX and C R Surgeon-General s Report, June 30th, 1900 pp 205 and 206

1901 —XXX. Dr W Findlay and Dr J W Findlay, THE LANCET Feb 22nd 1902, p 506

TABLE I.—*Synoptical Table of the Cases*

Cases from the literature		14
Cases collected but not published—		
a With complete details	40

53		E	76		E

Virus E = 18 cases; E or A = 4 cases; 8 = 1 case I = 1 case; total, 24 cases

The large number of cases in the year 1901 indicates that some exceptional condition existed that changed an unimportant and infrequent complication into a very important and frequent one.

The occurrence of tetanus as a complication of vaccination has been variously explained as follows.

1. *That it is an accidental secondary infection of the vaccination sore*—Those holding this view think that the complication depends upon conditions ever present and only to be expected and that its deplorable occurrence can be prevented by the exercise of greater skill and caution in the performance of the operation of vaccination and in the subsequent treatment of the wound That such a micro-organism as the tetanus bacillus the natural habitat of which is the soil and which occurs widely disseminated in nature, may occasionally be able accidentally to find its way into vaccination lesions cannot be gainsaid. It is certainly possible, and may occasionally happen, as, indeed the scattered cases in the literature seem to prove, but there are very cogent reasons opposed to the view that the many cases of 1901 can be so explained, and to content one's self with this simple explanation may be to fall into egregious error for if tetanus does thus occur it should do so in all parts of the world and with more or less regularity

The various indices to the medical literature are without any references to cases of tetanus following vaccination in most European countries. A communication from the Imperial Health Office of Berlin informs me that the complication is *unknown in the German Empire* Letters from the Pasteur Institute at Paris the Pasteur Institute at Lille and the French Institute inform me that the complication is *unknown in France* No cases appear to have occurred in Italy Russia, Austria, or other European countries, *so that* we are engaged in the consideration of a complication that is chiefly American, has become important within a year and was epidemic in the month of November 1901.

2. *That the occurrence of the complication depends upon a local prevalence of the tetanus germs*—The epidemic in Camden has been attributed to germs in the dust of that city in which there had been a prolonged period of dry weather Were this the true explanation we should find ordinary traumatic tetanus occurring more frequently than usual. See tables of statistics of Camden and Philadelphia Health Departments. This is however not the case, as aside from the vaccination cases there were fewer than the usual number of cases both in Camden and Philadelphia. Further while it is true that a greater number of cases of tetanus following vaccination occurred in Camden than in other places of equal size the occurrence of tetanus following vaccination has too wide a geographical distribution to be explained in this way

Cases are reported from 17 different States in the United States, from the Dominion of Canada, Porto Rico the Philippine Islands Cuba &c.

TABLE III.—*Report of the Board of Health, Room 610 City Hall, Philadelphia March 4th 190– —Deaths from Tetanus*

Months	1897	1898.	1899	1900.	1901.
January	6	5	0	4	3
February	1	4	3	1	1
March	4	2	2	3	0
April	1	1	0	4	2
May	1	4	3	3	1
June	3	3	3	1	1
July...	1	1	10	6	6
August	3	1	7	5	1
September	3	1	3	1	2
October	1	3	5	5	5
November	1	2	2	1	4
December	3	2	3	3	3
Totals	23	29	41	37	29

Note.—This table is of but small value as it shows no apparent increase of tetanus during the year 1901 and shows only 29 reported cases in all whereas I have been able to collect nine fatal cases resulting from vaccination Should we subtract those we would find much less traumatic tetanus than usual in Philadelphia during that year The table certainly shows very little, but fails to show that because of atmospheric or telluric conditions tetanus was exceptionally prevalent in Philadelphia during 1901.

TABLE IV.—*Report of the Health Department of the City of Camden.—Deaths from Tetanus.*

—	1901	1900	1899	1898	1897	1896	1895	1894	1893	1892	1891	1890
January	—	—	—	—	—	—	—	—	—	—	—	—

June	—	—	—	—	—	—	1	—	—	—	—	—
July	1	—	—	—	—	—	—	—	—	—	—	—
August	—	—	—	1	—	—	—	—	—	—	—	—
September	—	—	—	1	—	—	—	1	—	—	—	1
October	—	—	—	—	—	—	—	—	—	—	—	—
November	9	—	—	—	—	—	—	—	—	—	—	—
December	1	1	—	—	—	—	—	—	—	—	—	—
Totals	11	1	1	3	1	—	1	1	—	—	1	1

Note.—I was able to collect 11 cases of tetanus following vaccination in Camden and one case of traumatic tetanus occurred about the same time making a total of 12 cases The table shows 11 deaths. Three of the vaccination cases recovered so that there is here a slight difference between my collected cases and the report of the Health Department The eight fatal vaccination cases, plus the fatal traumatic case subtracted from the 11 reported fatalities leave us two cases unaccounted for—a difference not sufficient to show any greater general prevalence of the disease than occurred in 1898.

That geographical conditions may exert a pronounced influence upon the occurrence of the tetanus which is known to be particularly prevalent in certain districts. Thus it is said that Cuba and Porto Rico have soils particularly rich in tetanus bacilli and that Long Island has a similar dangerous soil. That such an influence is important is however very doubtful as from the so-called dangerous localities very few cases have been reported (three Cuba three Porto Rico and two Long Island) (see table.)

3 *That carelessness in the treatment of the vaccination wound facilitates accidentally secondary infection with tetanus* —While this has a ring of genuineness about it, and is doubtless true in some of the scattered cases, the argument is extremely unconvincing when applied to the cases of 1901 For 100 years vaccinations have been performed with a total disregard to cleanliness and asepsis in all parts of the world, on all classes of people, in towns and cities, by careless and careful physicians, upon clean and dirty persons, without the use of any dressing, yet during these many years tetanus has remained almost an unknown complication. We cannot conceive of any difference between the social conditions of the present and those of the past that are not immensely in favour of the present, yet it is at present that we find tetanus epidemic.

In our own country greater care is undoubtedly exercised at the present time than heretofore, and in those countries in which because of ignorance and poverty, the same social conditions prevail at the present time that existed a hundred years ago—as, for example, among the peasantry of Europe—we find tetanus practically unknown.

Vaccination wounds are treated with much greater care at the present time than ever before, and it is now becoming recognised that vaccination is an operation, and that to free it from the common dangers of all operative manipulations cleanliness and care are essential. We therefore find that at present the skin is cleansed and disinfected and the lesion itself protected and subsequently dressed with a care never dreamed of a few years ago, yet when we come to examine the details of those cases which have come within our knowledge we find that this care of the wound appears to be without influence upon the occurrence of tetanus, for while many cases have occurred among ignorant and filthy children, in an equally great number of cases more than ordinary care seems to have been exercised Thus one case occurred in the person of an adult sister of a physician in Cleveland, Ohio Both the patient and the operator were refined and cultured people, were apprehensive of the results, and exerted unusual precautions, yet despite all death from tetanus followed this vaccination Here let it be said that the virus associated with so many cases (virus E) was used.

The ignorant and filthy people of the island of Porto Rico, with no knowledge of hygiene or personal cleanliness, living in a place reputed to be extremely dangerous because of tetanus bacilli in the soil, were vaccinated by the United States authorities after the occupation of that territory, and out of some 800,000 vaccinations three cases of tetanus, two of which are very doubtful, are reported by Dr George G Groff

4 *The use of a shield to protect the vaccination wound has recently become quite common and has been blamed for the occurrence of tetanus* —The shield has, however met with violent and perhaps justifiable condemnation, on the ground that the pressure of its edges and of the adhesive plaster bandages by which it is held in place obstruct the lymphatic circulation and increase the severity of the wound and the danger of infection, also that the shield induces anaerobic conditions, so that by some the occurrence of tetanus has been blamed upon the shield Upon looking over the reported cases, however, we find so few in which shields were used that they seem to have no influence upon the occurrence of the complication

THE RELATION OF TETANUS TO THE VACCINE VIRUS.

With the evolution of vaccination as a prophylactic measure certain changes in technique have been gradually introduced. Thus bovine virus has now displaced the arm-to-arm and human scab vaccinations previously practised, and within the last quarter of a century the use of human virus has been almost entirely given up Can it be that the danger from tetanus has something to do with the bovine virus? In a few of the early cases drawn from the literature tetanus followed the use of human virus That the bovine virus is at fault seems possible when we consider that it is only in the last half century that cases of tetanus have occurred, yet it can scarcely be at fault in itself, as bovine virus is the only form employed in Belgium, Germany, France, and other European countries where no tetanus has occurred While it is suggestive that the first cases of tetanus reported in the literature make their appearance about the time bovine virus began to come into general use, it is not true that the number of reported cases increased in proportion to the popularity of the bovine virus for from 1852, when the first case I have found makes its appearance in the literature, until 1901 only isolated cases are reported, usually at intervals of years

The next step in the evolution of vaccination was the improvement in the quality of the virus, suggested by Copeman in 1891, by which glycerine was permitted to act for some time upon the virus for the purpose of destroying the undesirable micro-organisms it contained By the use of the glycerine a bacteria free virus may thus be secured This improved virus made slow but steady progress, until at the present time it has attained the greatest popularity and bids fair to replace all other forms It is used almost exclusively in Europe and has made very large inroads into America.

The glycerinated virus is so new, having been in use but 10 years and in common use little more than five years, that we are scarcely able to express a positive opinion regarding its advantages and disadvantages The advantage of having the contaminating bacteria destroyed by the glycerine is indisputable, the disadvantage of occasionally having the glycerine act so long that the specific germs of vaccinia are killed and the virus made inert is also indisputable That at times when the demands upon the manufacturer are exceptionally great the virus mixed with the glycerine might be placed upon the market before the necessary time had elapsed for the contained bacteria to be killed is a somewhat grave danger These possibilities have somewhat lessened the confidence with which the preparation is received and used by many practitioners

When we come to investigate the cases of tetanus concerning which information is at hand we are somewhat startled to find that a large number of them have succeeded *the employment of this supposedly best and most refined* preparation. This point will be discussed below

It must also be pointed out that the epidemics of tetanus which are *the subject of this paper occurred at a time* when an almost unprecedented demand for virus taxed the output of the manufacturers to their utmost and must have tempted them to market partly refined" goods. It is not impossible that it was insufficient contact with the glycerine that permitted tetanus bacilli to remain alive in the virus, though as glycerine fails to kill tetanus spores it is doubtful whether this is the chief or sole error

TABLE VI.—*Showing the Relation of Tetanus to the Make of the Virus.*

Relationship to particular brands of virus—When an attempt is made to determine whether the employment of any particular brand or make of virus is succeeded by an unusually large number of cases of tetanus we discover that while an occasional case of tetanus has succeeded the use of the virus of nearly all of the large manufacturers, the great majority of the cases of 1901 have succeeded the use of a particular brand of virus and make us suspect that the tetanus bacilli were contained within it.

The brands of virus to be considered are called E D A S, W I, St, and Wd. Those called E A, and D are the products of the largest American manufacturers who it is not improbable do about an equal amount of business It is safe to say that these vaccines are all made with the exercise of as great amount of skill as present knowledge permits. No care or expense is spared to have these products perfect *We find however a remarkable discrepancy* in the results following their employment—a discrepancy that leads me to conclude that the tetanus bacillus is contained in the virus and distributed with it. Careful examination of the accompanying table will show the disproportion of cases.

The occurrence of 30 cases of tetanus after the employment of virus E suggests that tetanus germs were present in it in larger proportions than in any other though the occurrence of only 30 cases following the use of millions of doses of this virus indicates that the number of tetanus *organisms present is small* and the *occurrence* of the cases in groups that their distribution is irregular

The occurrence of cases in groups—In this connexion must be pointed out as interesting and significant the groups of cases that have occurred from time to time. Thus in Cleveland Ohio during 1901 we note the occurrence of four cases in Camden, New Jersey during October November and December 1901, the occurrence of 11 cases at Atlantic City about the same time five cases and in Philadelphia and vicinity nearly at the same time about 25 cases (and rumours). If we analyse the cases we find one vaccine (virus E) chiefly if not exclusively implicated. The most instructive group of cases that I have been able to study occurred in the Philadelphia Hospital In this institution with nearly 4500 inmates there was a threatened epidemic of small pox depending upon the admission of a case of small pox from the street. After one or two cases had developed within the institution it was decided to vaccinate every inmate, and the resident physician went systematically through the institution, vaccinating sick and well alike. The institution was thus vaccinated with the exception of the Men s Insane Department, the greater number of the inmates of which were obliged to wait a few days until a new consignment of virus arrived With this new consignment (virus E) they were then all vaccinated. *Upon looking up the statistics of the hospital* we find that in the insane departments, male and female, no case of spontaneous traumatic tetanus had developed within 12 years. *It is, in fact, not known that there* ever has been a case of traumatic tetanus developed within the walls of the institution, but this cannot be determined as the records prior to 12 years ago were destroyed by fire Succeeding the vaccination, however a group of tetanus cases, confined exclusively to the Men s Insane Department, occurred. Here five typical cases with trismus and opisthotonos and every marked symptom of the disease occurred all being followed by death four from trismus itself and one from pneumonia occurring immediately after a cessation of the spasms The occurrence of this outbreak occasioned much alarm so that every suspicious vaccination wound observed was thoroughly excised and treated antiseptically After this excision of the wounds 11 additional cases developed trismus and muscular rigidity though after the administration of enormous doses of antitoxin they all recovered In going carefully over the details of these cases I find that with one very doubtful exception (vaccinated with E or A) every patient who developed tetanus was vaccinated with the same virus which had caused tetanus at Cleveland Camden, Atlantic City and elsewhere (virus E) As the diagnosis of the 11 cases that recovered is somewhat questionable I have included them among the *rumours* and have not introduced them into the statistical tables. Should it be suggested that the occurrence of the cases of tetanus in groups depends upon the popularity of the virus in certain districts, as Philadelphia, Camden and Atlantic City where it was almost exclusively used and that in these districts some telluric, atmospheric, or other condition prevailed causing them to be more predisposed to tetanus than the country in general the idea should be at once dispelled by a few moments consideration of the statistics presented. Thus if we deduct from the 30 cases succeeding the use of virus F the six positive cases occurring in Camden the seven positive cases occurring in Philadelphia, and the three positive cases occurring in Cleveland, there remain against this virus a total of 14 cases which is greater than the sum total of all the cases referable to all the other viruses produced in the country thus showing that even where the cases are scattered and not in groups virus E has four times as many cases against it as any other virus and more cases than all the other viruses put together

In the accompanying table 40 cases are presented with exact information concerning the make and form of virus employed. Of these 40 cases 30 follow the employment of virus E 10 follow the use of all other forms combined and no single other virus has a higher number than three. This seems to show quite convincingly that there is something about virus E that is different from the others. In addition to these 40 cases with complete details I have eight additional cases in which it is known that one or the other of two viruses was used but in which it cannot now be certainly determined which of the two it was

TABLE VII.—*Cases of Disputed Virus where One or the Other of Names are Given.*

Cases	E	A	D	W	Wd	St
25	1	—	—	1	—	—
29	1	—	1	—	—	—
45	1	—	—	—	—	1
66	1	1	—	—	—	—
71	1	1	—	—	—	—
72	1	1	—	—	—	—
73	1	1	—	—	—	—
91	—	—	1	—	1	—
—	7	4	2	1	1	1

We find that in the cases of this group vaccine E figures in seven. If we assume which it would be fairly justifiable to do, that in all of these cases virus F was used, then the disproportion is changed from E 30 to all others 10 (30 10) to E 37 to all others 10 (37 10), thus making matters worse. If however we proceed on the reverse order and admit that

E may be erroneously charged with these cases we find the proportion E 30 to all others 18 (30 18), so that matters are but little improved for virus E Comparing E with the other viruses made by equally large houses the disproportion is, of course, much more striking than when comparing it with the sum of all others, thus —

$$\left.\begin{array}{l}\text{E 30 (without disputed cases)}\\ \text{E 37 (with disputed cases)}\end{array}\right\}\text{D 2.}$$

$$\left.\begin{array}{l}\text{E 30}\\ \text{E 37}\end{array}\right\}\text{A 2.}$$

$$\left.\begin{array}{l}\text{E 30}\\ \text{E 37}\end{array}\right\}\text{S 3}$$

It certainly seems impossible that if the viruses were of equally good quality such a disproportion as 30 2 and 30 3 could persist.

M I	1	0

If we refer to the chronological table given it becomes apparent that it is only occasionally that outbreaks of tetanus following vaccination occur The scattered cases in the literature and the few cases observed to occur after the employment of viruses of all makes may depend upon secondary infection. In the few cases contained in the literature in which tetanus succeeded arm to-arm vaccination this is very probably true, but it is impossible for this explanation to apply in the sudden appearance of 24 cases (without rumours) that developed during November, 1901. The only explanation that appeals to me is that while secondary infection of vaccination wounds occurs very rarely and while tetanus bacilli are contained in bovine vaccine in numbers large enough to produce tetanus occasionally, some times through accidents or carelessness unusually large numbers of tetanus bacilli get into the virus with resulting epidemics such as the one which is here considered. Granting the possibility of this it becomes of prime importance that the utmost precaution should be exercised in preparing the virus, and if possible that some new method should be adopted by which its manufacture shall be carried out with out the possibility of danger of this kind.

Dry and glycerinised viruses —The respective influence of dry and glycerinised virus upon the causation of tetanus is shown by reference to Table VI, where it is shown that seven cases followed the use of dry points, 11 the use of glycerinised points, and 22 the glycerinised tube virus This proportion (seven to 33) appears to be convincingly in favour of the dry virus, but we find an error resulting from virus E All three forms of virus E have been followed by tetanus in the respective proportions of dry points three, to glycerinised points 10, and glycerinised tube virus 17 If we entirely omit virus E from the consideration we find the totals of all other viruses to be —

$$\begin{array}{l}\text{Dry points}\\ \text{Glylcerinised points}\\ \text{Glycerinised tubes}\end{array}\quad \left.\begin{array}{l}4\\ \left.\begin{array}{l}1\\5\end{array}\right\}6\end{array}\right\} = 4\ \ 6$$

The proportion of four dry to six glycerinised is about correct when we remember that the glycerinised is the popular virus at the present time. This seems to show that there is no important disproportion in favour of dry over glycerinised virus as regards the occurrence of tetanus.

The source of the tetanus bacilli in virus —When we consider the distribution of the tetanus bacillus in nature we find it in the soil chiefly whereon it has been well fertilised and in manure. The tetanus bacillus is, no doubt, frequently swallowed by herbivorous animals in browsing upon the surface of the ground, and the anaerobic conditions for its growth being excellent we find that the intestines of herbivorous animals commonly contain large numbers of the bacilli which escape with the evacuations to be again deposited upon the soil in increased numbers The first source of danger, therefore, by which vaccine virus can be contaminated is the manure of the calf, the next source the dusts arising from the dry manure and the soil, both of which may be brought into the stables with the hay or upon the animals

When large hay fed animals are employed for the manufacture of virus the manure is certainly a source of danger, but in stables where sucking calves are used for the purpose fewer tetanus bacilli are present in the excrement However, Huddleson found them present in the fæces of 8 per cent. of the small calves used in the laboratory of the Health Department of New York It is evident that from these sources opportunities for the entrance of tetanus germs into the vaccine virus occur, but as a matter of fact no one has yet succeeded in finding them in the virus This indicates that their number must be so small that in the distribution of the virus in tubes and on points hundreds or thousands of tubes escape where one is contaminated It must be unusual for many tetanus germs to be implanted at the time of vaccination but no doubt such implantations can and do occur

The incubation period —The period of incubation or ordinary traumatic tetanus varies from a few hours to several weeks (see chart), according to statistics derived from the study of a large number of cases

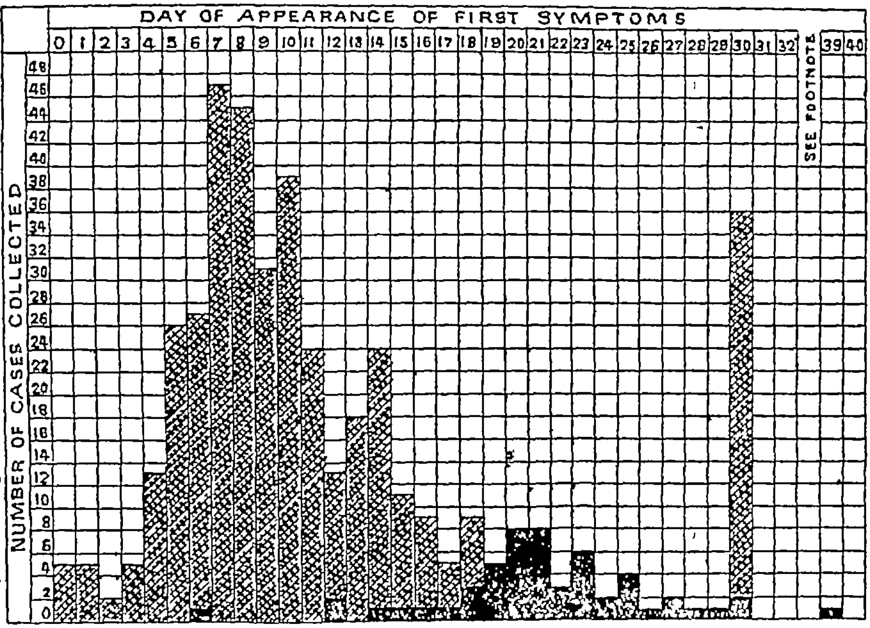
TABLE IX.—*Tetanus Cases, showing Incubation Period*

Shortest period	6 days
Longest period	39 ,,
Average	22 ,,
For points—	
Shortest period	16 ,,
Longest period	30 ,,
Average	23 ,,
For glycerine virus—	
Shortest period	6 ,,
Longest period	39 ,,
Average	22 ,,

The usual incubation period varies from seven to nine days In the vaccination cases—that is in cases of tetanus following vaccination—we find the shortest period of incubation to be six days, the longest 39 days, and the average 22 days It is thus seen that tetanus following vaccination appears on the average about two weeks later than ordinary traumatic tetanus. This is the chief weak point in my argument and I think that if this error could be eliminated it would at once be conceded that the remaining facts are indisputable The prolonged incubation is usually interpreted to signify that the infecting organism entered the vaccination as a secondary infection. In truth, however, how rarely do superficial ulcerations become infected with tetanus Did anyone ever hear of a sudden paroxysmal outbreak of 61 cases of tetanus in one year following the infection of leg ulcers, furuncles, mosquito bites &c, even when cleanliness was not observed?

I think after the statistical demonstration that this secondary infection theory must be looked upon as a misinterpretation and that the fact probably is that the tetanus bacillus being ingrafted into the skin at the time of vaccination fails to find suitable conditions for its growth until the development of the vaccine lesion paves the way for it by the local destruction of tissue. This enables us to add to the usual period of incubation an additional period (a couple of weeks), during which the wound has been prepared for the implanted organisms to grow, thus bringing the entire period to the length usually observed in the vaccination cases. An examination of Table IX. shows that no difference exists between dry vaccine on points and glycerinised virus regarding the length of the incubation period.

In nearly every case in which I have succeeded in securing details I learned that the vaccination "took well." This may not be without significance, though it may be interpreted in several ways. It may mean that those vaccinations in which marked local lesions occur are those in which secondary infection has the best chance of occurrence If so, it means that severe vaccination lesions are dangerous and that mild viruses should be used, the multiple insertion of a mild virus being preferable to a single insertion of an active virus It may also mean that the lesion was caused by an impure virus in which the tetanus bacillus might be contained as well as other organisms Lastly, and I think truly, it



Period of incubation.—The columns in light shading represent cases of traumatic tetanus (387 in number); the black columns represent cases of vaccination tetanus (64 in number). In the original diagram the eight vertical columns with the headings 31 to 38 inclusive were blank; five of these were omitted in the reproduction as above indicated for economy of space.

may mean that it is only when such local lesions occur that the *implanted* tetanus bacilli can find conditions suitable for their development.

Reference is again to be made to the chronological development of the cases, by which it will be observed that the majority of cases occur at times when, because of agitation concerning small pox, the demands for virus are great. This being the case it is not impossible that vaccine viruses are sometimes marketed prior to the time when the action of the glycerine has extinguished the life of the bacteria in the virus and with less than the customary precautions regarding excellence of quality.

CONCLUSIONS.

The following conclusions seem justifiable. 1. Tetanus is not a frequent complication of vaccination. 2. The number of cases observed during 1901 was out of all proportion to what had been observed heretofore. 3. The cases are chiefly American and occur scattered throughout the eastern United States and Canada. 4. The cases have nothing to do with atmospheric or telluric conditions. 5. A small number occurred after the use of various viruses. 6. An overwhelming proportion occurred after the use of a certain virus (E). 7. The tetanus organism is in the virus in small numbers, being derived from the manure and hay. 8. Occasionally through carelessness or accident the number of bacilli becomes greater than usual and may lead to the epidemic occurrence of tetanus. 9. The future avoidance of the complication is to be sought for in greater care in the preparation of the vaccine virus.

NOTE.—Since writing the above the final proof needed to complete the argument seems to be given by Dr. Robert M. Willson who contributed to the Philadelphia County Medical Society on April 23rd, 1902, the information that he had discovered tetanus bacilli in large numbers in a vaccine virus made about the time of the epidemic of 1901. This bacillus which was microscopically demonstrated to the society was virulent for the small laboratory animals.

Philadelphia.

A SUCCESSFUL CASE OF GASTRECTOMY FOR CARCINOMA OF THE PYLORUS AND LESSER CURVATURE OF THE STOMACH

BY G. A. SYME, M.S., M.B. MELB., F.R.C.S. ENG.,
LECTURER ON ANATOMY, MELBOURNE UNIVERSITY; SURGEON TO ST. VINCENT'S HOSPITAL, ETC.

THE operation of gastrectomy is on its trial. Mr. W. Watson Cheyne and Mr. F. F. Burghard in their recently published "Manual of Surgical Treatment" say: "Although the entire stomach has been removed for cancer with temporary success, we cannot think that the number of cases in which this can be done will be large, nor do we look upon the operation as at all a favourable one." They do not even describe the operation, as "if the growth be sufficiently large to warrant such a severe procedure it is practically beyond hope of immunity from recurrence."

In the following case the operation as performed was not such a very severe procedure, and though it remains to be seen whether the growth will recur there is reason to believe that it has been radically removed. It seems to me that in all cases of gastric carcinoma, where operation *is advisable* at all, gastrectomy is indicated, as it having been proved that the stomach is not essential for digestion, the more complete its removal the greater should be the probable immunity from recurrence, while the risk is not proportionally increased. If at all possible it is, however, wise, for physiological reasons as well as for ease in operation, to leave a small portion of healthy stomach.

As compared with pylorectomy the operation as performed in this case was easier and took less time, because there was less stomach surface to suture. The cut edges were easily and rapidly brought together with continuous silk sutures (through all the coats) and then the duodenum was implanted into the very small surface of the fundus that was left Had there been difficulty in approximation I would have closed the duodenum and attached the jejunum The microscopical examination subsequently showed that where cut the stomach was perfectly normal, though the growth was disseminating widely along the lymphatics

For the detailed notes and for careful attention to the after treatment of the case I am indebted to Dr Murphy, resident medical officer at St Vincent's Hospital, Melbourne, to which institution the patient, a married woman, aged 55 years, was admitted on May 8th, 1902, under my care. She complained of pain in the abdomen and vomiting She stated that except for occasional pain in the left shoulder she had enjoyed good health until seven months previously when she began to suffer from indigestion and flatulence. Five months previously she began to vomit, and had continued to vomit, at intervals of one or two days, up to the time of her admission. The vomiting generally occurred at night, and she brought up food taken eight or 10 hours previously, as well as acid watery matter She had lost weight.

On examination she was found to be a spare active woman, looking younger than her years, but distinctly emaciated Just above the umbilicus was a hard moveable tumour of the size of a mandarin orange The stomach was dilated Her pulse was 90 and rather small in volume but strong Her temperature was 99° F. All the other organs and the urine appeared to be normal On May 11th she was given a test-meal which was withdrawn four and a half hours afterwards and examined by Dr Wilkinson, assistant demonstrator of physiology, Melbourne University, who reported that the meal was considerably digested and that no free hydrochloric acid could be found On the 13th and 14th the stomach was washed out and again on the morning of the 15th, when the operation was performed under ether anæsthesia.

The abdomen was opened in the mid line, between the ensiform appendix and the umbilicus The pylorus was found to be occupied by a hard growth which extended along the lesser curvature and in radiating lines over the anterior stomach wall. No enlarged glands could be detected The cardia appeared to be free from disease. After a little deliberation it was decided to remove the stomach The abdominal incision was enlarged and the stomach was delivered from the abdominal cavity and packed off with plain sterilised gauze, wet with hot sterilised normal saline solution. The small omentum was ligatured off in sections with silk (and the pyloric and gastric arteries secured) at a distance of about one and a half inches from the lesser curvature and then divided. The great omentum was ligatured and divided in a similar way The cardiac end of the stomach was then clamped obliquely in long forceps (not covered with rubber) and the stomach on the distal side of the clamps and about one and a half inches from them was tied round with a piece of rubber tubing The stomach was then divided between the clamps and tubing, so that the whole of the lesser curvature up to the œsophagus was removed and the greater part of the greater curvature, leaving about two and a half inches of cardia attached to the œsophagus The stomach and growth were turned over the abdominal wall to the right and out of the way and covered with hot sterile gauze wet with saline solution. The cut edges of the stomach beyond the clamps were disinfected and then sutured with a continuous silk suture through all the coats and then a continuous Lembert silk suture was passed through the sero muscular coat, invaginating the previous one Further search was then made for infected glands and some, though not obviously hard or enlarged, were removed from near the pancreas The duodenum was then clamped about one inch from the growth and a rubber ligature was tied round it nearer the growth, the duodenum was divided between the two and the stomach and growth were removed. The cut edges of the duodenum were disinfected and approximated to the remaining portion of stomach and œsophagus and laterally implanted on it. One wall of the duodenum was attached to the stomach by a continuous serous suture, the ends being left long The stomach was then incised and the cut edge next the suture was attached to the adjacent duodenal wall with a continuous suture through all the coats and this was carried all round The serous suture was then finished off. The exposed viscera were flushed with hot saline solution and replaced The abdominal incision was then closed with through and through sutures. An enema of one pint of saline solution and one ounce of brandy was administered and the patient was put to bed The operation took a little over an hour The following diagram roughly shows the amount of stomach removed and the position of the growth. The shock was not great and the patient rallied well She was fed by nutrient enemata, alternating with saline, every four hours

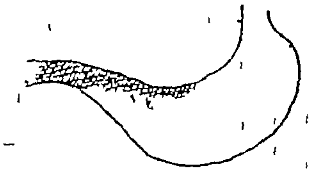


Diagram of stomach showing portion affected by growth shaded

On May 16th enemata (nutrient and saline alternately) were administered every four hours and one fortieth of a grain of strychnine was given every four hours The temperature was 101°, the pulse was 112, and the respirations were 24 The patient was feeling well. On the 17th one drachm of water was given occasionally by the mouth. The temperature was 100°, the pulse was 116, and the respirations were 20 From two drachms to half an ounce of sterilised water or peptonised milk was given every two hours by the mouth Enemata were administered every four hours On the 18th her general condition was good. The temperature was 99°, the pulse was 80, and the respirations were 20 From one drachm to half an ounce of water, peptonised milk, or broth was given every hour Nutrient enemata were administered every six hours On the 19th the patient was feeling very well The temperature was 99°, the pulse was 80, and the respirations were 20 Half an ounce of peptonised milk, water, broth, or beef-tea was given every hour No discomfort was experienced after taking it. An enema was administered every eight hours The bowels acted on this date On the 20th the patient was feeling very well The temperature was 99° and the pulse was 80 One ounce of water, peptonised milk, beef-tea, Benger's food, or jelly was given every hour and occasionally she had small drinks On the 21st the temperature was 99° and the pulse was 80 She was given one and a half ounces as above or solution of plasmon every one and a half hours Two enemata were administered in the 24 hours On the 22nd the temperature and pulse were normal She was taking one and a half ounces of nourishment every hour with occasional drinks 10 minims of dilute hydrochloric acid were given with the nourishment She did not like taking the acid. On the 24th the temperature and pulse were normal She was taking two ounces of nourishment every hour with occasional drinks. On the 25th she was taking three ounces every two hours and one drachm of somatose every three hours The hydrochloric acid was discontinued, she said that she felt better without it On the 28th she was having five ounces of nourishment every two hours with a little bread crumb and bread and butter She experienced no feeling of indigestion. All the sutures were removed On the 30th she was taking six ounces of milk, bread and milk, custard, somatose, fish, or arrow root every two or three hours. On June 3rd the diet was as follows six ounces of liquid and occasionally tripe, mashed potatoes, boiled eggs, and bread and butter She did not suffer from indigestion The temperature and pulse were normal and she was feeling very well On the 4th she was taking the same articles of diet as on the 3rd, also grilled steak, mashed potatoes and cauliflower, and biscuits On the 12th she was eating ordinary food and could take as much as she did when she was quite well. She did not suffer from indigestion No acid or pepsin was given She said that she could feel the food going into the intestine. She was increasing in weight and strength and was walking about. She stated that she felt very well On the 17th she was discharged.

The patient and the specimen removed were exhibited at the July meeting of the Medical Society of Victoria, and the following report on the specimen has been received from Dr H. G Chapman, demonstrator of pathology, Melbourne University "The part removed consisted of the first part of the duodenum, the pyloric end, and a portion of the cardia and fundus, of the stomach The removed duodenum measured 40 millimetres from the sphincter pylori The stomach has been divided obliquely, the lesser curvature being cut 90 millimetres and the greater curvature 270 millimetres from the pyloric groove At the pyloric orifice and extending into the duodenum for about 10 millimetres and towards the stomach walls, especially along the lesser curvature was a diffuse thickening fading imperceptibly towards the stomach walls The cut edges were free from thickening On section the cut edge of the diffuse thickening showed a white downgrowth from the mucous to the muscle layer Sections under the microscope showed a carcinomatous downgrowth from the glands through the muscularis mucosa into the submucous coat, but nowhere directly passing into the muscular coat, which was, however diffusely infiltrated with cancer cells lying along the lymphatic vessels In the deeper part of the mucous membrane all glandular structure was lost in a diffuse mass of carcinoma. In the submucosa on the edge of the cancerous infiltration were collections of small round cells betokening irritation. There had been a considerable dissemination along the lymphatics, accounting for the general thickening and giving rise to early gizzard like cancer Sections taken close to the incision at the lesser curvature were free from growth with the mucous membrane everywhere clearly defined and the muscle free from infiltration.'

Melbourne.

A CASE OF HÆMOPHILIA IN A WOMAN WITH SYMPTOMS OF DEFECTIVE CIRCULATION IN THE LEGS AND THREATENED GANGRENE OF THE TOES, DEATH WITH CEREBRAL SYMPTOMS

BY JOSEPH A. ARKWRIGHT, M.D CANTAB.

THE patient was a single woman, aged about 30 years at the time of her death in November 1901 of fair complexion tall large-boned and well developed None of her relatives in previous generations were known to have been bleeders She had two sisters, both alive, one aged about 26 years who suffered from attacks of dyspepsia and vomiting which lasted for weeks or months, but who had good health between the attacks though at one time she was very anæmic, the second sister was 13 years old and had very good health. There was one brother 20 years of age, who had hæmophilia but not very severely he had had excessive swelling and ecchymosis about one knee from a slight injury and swelling and pain in the hip-joint after a very slight injury On other occasions he had had troublesome bleeding from a cut on the thumb and great swelling and ecchymosis which continued to increase for some days after a bruise of the upper arm. The present patient had always had a tendency to anæmia and had suffered from dyspepsia. In 1890 a superficial cut on one finger bled for two or three days, but some years ago she had a tooth extracted without excessive hæmorrhage. On Sept. 15th 1893, a right lower first molar was extracted and the next day the bleeding had not stopped and the patient was very pale and faint the hæmorrhage was arrested by applying pressure and the strong solution of perchloride of iron. On Nov 14th 1893, the right upper second bicuspid was extracted and the bleeding continued till the next day when it was stopped in the same way as before, but on the 16th it recurred till it was finally arrested by the same means, tincture of hamamelis being also taken internally On Nov 5th 1894 she complained of pain in the lower limbs there were aching pains in the left thigh and hip chiefly in the anterior part, as though in the bone" which had been present and had never quite left her for eight weeks sometimes they were severe especially at night and they had been worse during the last month there had also been pain in the right thigh like that on the left side, especially along the anterior aspect and for the last 24 hours also in the right hip and in the sacrum There was no tenderness on pressure except over the front of the femur on the right side just above the knee. The patient's temperature was normal in the daytime. About the middle of November the pains began to get better and by Dec. 25th she was very much better but there were still some pains in the limbs. In April 1898 she complained of bad neuralgic" pains in her right arm which improved after she had taken Blaud's pill and arsenic for a short time. On April 25th 1898 she twisted her right ankle slightly in getting over a stile On the next day the ankle was swollen and on the 28th the ankle had become much more swollen in spite of rest and the skin was tense and hot, there was also much ecchymosis On Sept. 1st tense ecchymosed swelling of the calf and ankle followed a slight injury In November the bleeding from a slight cut on the finger lasted for two or three days and was then only arrested with some difficulty by very hot water and tight bandaging In the summer of 1900 the left leg was noticed to be colder than the right and a variable purple mottling was almost constantly present on the skin of the left leg below the knee. These two symptoms persisted from this time onwards In the very cold frosty weather of the winter 1900-1901 the ends of the toes on the left foot became black and purple and gangrene threatened This condition passed off with rest and elevation but returned several times after walking a short distance at one time there was some ulceration The purpuric mottling about this time spread from the leg on to the left thigh hip, buttocks, and the opposite (right) hip and outer side of the right thigh For four months in the summer of 1901 she was in the General Hospital Birmingham and whilst there the toes were at one time very bad but later regained their natural appearance. A relapse again occurred after a journey and walking a little and the toes became painful and discoloured While in hospital she also had an attack of general rheumatic (?) pains in the legs and arms especially in the left elbow with raised temperature. On August 28th 1901, the toes were less well after sitting out of doors in rather cold and damp weather On Oct 1st a sharp attack of bleeding from the gums occurred without any known exciting cause the gums were not at all spongy or sore. On Oct. 7th the patient was found to be better with regard to the pain and the circulation in the legs but lately the hands had been colder and sometimes the fingers blue and the hands mottled with a purplish colour both the radial arteries felt small the general nutrition and appearance were good and the appetite was fair Both the legs were mottled and purplish there was no raised erythema. The left leg was much more mottled than the right and the mottling was most over the malleoli and on the dorsum of the foot. The right great toe was dusky in colour the left middle toe was black at the end and a little dried serum was to be seen on the surface but no moist discharge was ever noticed There was no pain and both feet were warm but they were kept well wrapped up and raised the feet easily became cold and if on the floor for long became painful but not hot. The left dorsalis pedis artery was felt beating but the left posterior tibial artery could not be felt, the right dorsalis pedis artery was not felt but the right posterior tibial was felt beating On Oct. 15th the left little and middle toes were seen to be almost black. On the 17th these toes were slightly better in colour and the right foot had only some mottling on the dorsum no duskiness of the toes. The left foot and leg were noticed to tremble and twitch (this was seen to affect especially the tendons of the tibiales muscles) when the limb was held up unsupported but the right foot and leg did not tremble The left knee jerk was exaggerated the left plantar reflex was absent, the right knee jerk was very much exaggerated a tap set up clonus the right plantar reflex was very feebly obtained Ankle clonus could not be obtained on either side. On Nov 1st, after the leg had been lightly massaged daily for a fortnight the feet were thought to have kept warmer and the toes a better colour on the whole On the morning of the 4th the patient felt better but had complained of a headache for the last two days and the feet were rather colder but this was usual just before the menstrual period which was due that day In the evening at 7 30 while talking to a friend, the mouth began to be drawn to one side then the head to one side, and then she said she was choking and put her hands to her throat Soon after convulsions on one side of the body and twitching of the left arm and leg began and she sweated profusely she spoke and complained of pain over her eyes At 8 30 P.M. there was conjugate deviation of the eyes to the right the pupils were small and equal and reacted to light one eyeball was slightly bulging She was dull mentally but spoke sensibly once occasionally she became restless and excited throwing her limbs about and passed urine under her After this she went to sleep but woke again and was convulsed several times in the night struggling" much latterly Her breathing became noisy at 4 A.M. on Nov 5th and she died at 5 15 A.M.

This case presented an unusual combination of symptoms The tendency to bleeding was shared by a brother, and though not extreme and not traced to a former generation it resembled hæmophilia. The coldness and deficient blood-supply to the lower limbs had some resemblance to Raynaud's disease, but the symptoms were too persistent and progressive and did not intermit with sufficient completeness to agree with the classical description of that disease, moreover, the symmetry was very imperfect. Exacerbations were generally excited by the use or dependent position of the legs and were not truly paroxysmal The mottling of the skin affected the lower limbs high up and even the buttocks and consequently the circulation must have been defective in these parts This suggests some obstruction to the main arteries of the limbs, but the arteries supplying the feet were also not all felt beating in the usual situations An arteritis, or constriction of the smaller arteries, possibly due to nervous influence, seems to be the most likely explanation of the symptoms, but this leaves the ultimate cause and the connexion with the tendency to hæmorrhages unaccounted for Perhaps the neuralgic pains in the limbs were due to deficient blood supply or deep hæmorrhages The final cerebral symptoms preceding death are best explained by meningeal hæmorrhage determined by the increased blood pressure preceding the menstrual period, but intracranial hæmorrhage does not appear to be a recognised cause of death in hæmophilia.

Halesowen

THE ULTIMATE RESULTS IN A SERIES OF 76 CASES OF FRACTURE OF THE TIBIA AND FIBULA.

By R. W MURRAY, F R.C S Eng,

SURGEON TO THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL

During the last few years several articles have appeared in the medical journals drawing attention to the treatment and prognosis in the case of simple fractures of the bones of the lower limbs Fractures of the tibia and fibula have perhaps received the chief attention, and although most of the surgeons who have recently written upon this subject express themselves as being dissatisfied with the ultimate results obtained after the so-called ordinary methods of treatment, yet it would be difficult to find any two surgeons who entirely agree as to some of the important details in the remedies suggested For example, one surgeon, believing that the impaired utility of the limb after a fracture of the bones is largely due to hæmorrhage into, and inflammatory thickening of, the soft parts at the seat of the fracture, advocates the early employment of massage. Another surgeon, believing that spasmodic muscular contraction is a very important factor in preventing the correct apposition of the broken fragments, practises tenotomy, while a third surgeon, being convinced that the subsequent utility of the injured limb will be directly proportionate to the accuracy of the reduction of the fracture, does not hesitate to cut down upon the fractured ends and to fix them together with wire or a screw All are, however, agreed that the age of the individual is one of the most important factors as regards prognosis It is a well-established fact that if a child sustains a fracture of the femur or of the tibia and fibula the probabilities are that the ultimate utility of the limb will be in no way impaired.

My personal experience of fractures of this kind in children has been somewhat extensive, for in the 10 years during which I was connected with the Liverpool Infirmary for Children I forcibly straightened—or, in other words, broke—more than 1400 crooked legs In all these cases the fracture produced was a simple fracture either of the lower end of the femur or of the tibia and fibula, according as the deformity corrected was a knock-knee or a bowed leg The after-results were in every way satisfactory in respect to the union of the fracture and the position and utility of the limb When, on the other hand, a fracture occurs in an adult the prognosis for obvious reasons is much more grave and the object of this communication is to try to arrive at a fair estimate of the after-results from these injuries. My original intention was to include fractures of the femur, patella, tibia, and fibula, but for the present I propose to limit my remarks to the treatment and prognosis after simple uncomplicated fractures of the tibia and fibula. For this purpose I wrote to every patient who had been treated for a fractured tibia or fibula at the David Lewis Northern Hospital during the last five years, and I regret to say that the number of patients who responded to my request to attend at the hospital bore a very small proportion to the number of post-cards sent. However, I succeeded in finding at their own homes many of those who did not come, and although the numbers thus obtained are comparatively small the results are interesting and, I think, well worth consideration As the majority of these patients were not under my own care I have to thank my colleagues, Mr Chauncy Puzey and Mr Damer Harrisson, for kindly allowing me to make use of their cases and I am pleased to have this opportunity of expressing my great obligation to Mr Arthur N Walker and Mr C Thurstan Holland for the time and trouble which they have taken in furnishing me with the x ray photographs

In the hospital where these cases were treated, situated as it is close to the Liverpool Docks, we have to deal with a large number of fractures (about 350 annually) and as we therefore have a somewhat exceptional experience in the treatment of broken legs I hope that I am justified in assuming that the results obtained are at least equal to the average results obtained elsewhere

What, then, do these results amount to? I have succeeded in learning the after results of 76 cases and a brief account of each case is given in the appended table In almost every instance the patient was an adult male and the fracture was a so called simple fracture and not complicated by a wound of the big blood vessels, by a dislocation, or by a joint being involved, except, of course, in some of the cases of Pott's fracture I have only included a few fractures in females because I wished to ascertain how far a man's wage earning capacity was interfered with after a simple fracture of the tibia and fibula, in other words, how long he would be off work and how far he would be able to resume his former employmemt This will, of course, depend very largely upon the man's trade The after-result might be entirely satisfactory if he is a tailor or a dock labourer and works on the flat, but the same result may be by no means satisfactory if the man is a sailor, an Everton forward, or a steeplejack. Whether we do or whether we do not, my belief is that we should be able in the majority of cases so to mend a broken leg that whatever a man's trade is he will subsequently be able to follow it.

The depreciation in the wage earning capacity of a labouring man after he has sustained an oblique fracture of the lower third of the tibia is said to be considerable and has been estimated at being somewhere between 40 and 60 per cent I am pleased to find that the results obtained at the David Lewis Northern Hospital, judged by these standards, have been very creditable But however creditable these results may be I sincerely hope that in the future they may be infinitely better, as I firmly believe they should be

Why is it that at the beginning of the twentieth century we are not able to mend broken legs better than we do? I believe that it is in a great measure owing to the fact that in hospitals fractures, as a rule, do not excite much interest, at all events not to be compared to the interest excited in treating a cancer of the pylorus or a cerebral tumour But surely it is better completely and permanently to restore the utility of a broken limb of a healthy man than to prolong the life of a cancerous patient for a few years Owing chiefly to the introduction of antiseptics the advances in abdominal and cerebral surgery have, even in my own time, been little short of marvellous, but the treatment of simple fractures at the beginning of this century is very much the same as it was at the beginning of the last So far as I have been able to ascertain, if a man with a simple fracture of the tibia and fibula, whether the fracture is oblique or not, be admitted into any hospital in England, the great probability is that after the fracture has been "set," with or without an anæsthetic as the case may be, the limb is fixed in a back splint with a vertical foot-piece and side splints I am perfectly well aware that other methods of splinting are employed, but the one which I have mentioned is, I believe, the most usual one.

I do not know whether any practising surgeons have ever had the curiosity to try the ordinary back splint with the vertical foot-piece on themselves, but I have and have found the

TABLE SHOWING THE ULTIMATE RESULTS IN 76 CASES OF FRACTURE OF THE TIBIA AND FIBULA

No	Age in years.	Date of admission to hospital	Fracture	Length of stay in hospital.	Period off work.	Result and remarks
1	55	January 1897	Pott's	5 weeks.	1 year	Very unsatisfactory; the patient walks with a stick and is unable to resume his former work of carter
2	65	April, 1897	Tibia and fibula (lower third oblique)	5	11 months	Patient working as before (boiler maker)
3	61		Tibia and fibula (lower third)	3	6 „	(porter)
4	45	July 1897	Pott's.	3	7	Patient not able to resume former work
5	38	August 1897	Pott's.	4	4	Patient working as usual (coal heaver)
6	37			4	2	„ (labourer)
7	50	September 1897	Tibia and fibula (middle third)	6	?	Patient working as before but lighter work as he cannot walk far (carter)
8	57	October 1897	Tibia and fibula (lower third, oblique)	6	6 months.	Patient working as before (porter)
9	27		Pott's	5	4	(carter)
10	47	November 1897	Tibia and fibula (lower third oblique)	8	4½	(driver)
11	43	January 1898.	Fibula (lower fourth)	7	4	(labourer)
12	39	January 1898.	Tibia and fibula (compound).	8	?	(polisher)
13	30	„	Pott's.	4	2 months.	(labourer)
14	28	February 1898.	„	5	4	Patient resumed former work (fireman) but limps and ankle is painful.
15	48	March 1898.	Tibia and fibula (lower third)	4	7	Patient working as before (labourer)
16	53	May 1898.	Tibia and fibula.	8	5	(stage-man)
17	66		Tibia and fibula (lower third)	6	5	Patient cannot go aloft as a rigger; working as a labourer
18	30	July 1898.	Tibia and fibula (lower third oblique)	4	3	Patient working as before (warehouseman) The seat of the fracture is distinct and some overriding of the tibia is present; there is slight shortening but not sufficient to cause lameness.
19	60		Tibia (lower third)	4	5 „	Patient working as before (carter)
20	32		Pott's.	3	3 „	Patient working as usual (labourer)
21	49			3	3	Patient working as before (overseer)
22	33	August 1898.	Tibia (lower third)	6	3	(porter)
23	38		Tibia and fibula lower third comminuted)	10	10 „	Patient working as before (mason). His foot swells after the day's work
24	38	September 1898.	Tibia and fibula (lower third)	4	3	Patient working as before (foreman)
25	22		Pott's.	3	3	(coal-heaver).
26	69	November 1898.	Tibia and fibula (lower fourth)	5	3	(sailmaker)
27	23		Internal malleolus.	4	3	„ (labourer)
28	21			5	4	
29	28	December 1898.		4	3	
30	19		Tibia and fibula (lower third)	4	3	„
31	50		Tibia and fibula.	6	4 „	„ (coachman)
32	30	February 1899	Tibia and fibula (lower third oblique)	5	?	Five months after the accident the patient was in the workhouse; leg and ankle swollen; unable to put foot to ground; walking with crutches.
33	61	„	Pott's.	4	7 months	Patient not able to resume former work as carter
34	22	„		3	2	Patient working as before (labourer).
35	33	March, 1899.	Tibia and fibula (lower third, oblique)	5	4	Patient walks fairly well, but with a limp; some overriding of fragments Working as before, but leg painful after a heavy day's work (labourer)
36	28	April 1899	Tibia.	3	3	The seat of fracture is distinct at the lower third of the tibia. Result is very satisfactory the patient working as before (labourer)
37	49	May 1899	Tibia and fibula (lower third oblique)	6	8	There is considerable callus at the seat of the fracture Patient not yet able to work walking with a stick (November 1899)
38	21		Tibia and fibula (middle third comminuted).	5 „	5	Patient not able to resume former work of mounting ladder and carrying bricks. Is working as a dock labourer
39	25		Tibia and fibula (lower third oblique)	5	8	Patient not able to resume work as leg is swollen and painful X ray photograph shows obliquity of fracture (labourer)
40	33		Pott's	4	4	Patient working as before (labourer)
41	17	June 1899	Tibia.	8 „	4 „	„ „
42	31	July 1899	Pott's.	3 „	2 „	„ (window cleaner)

TABLE SHOWING THE ULTIMATE RESULTS IN 76 CASES OF FRACTURE OF THE TIBIA AND FIBULA—(*Continued*)

No	Age in years	Date of admission to hospital	Fracture	Length of stay in hospital	Period off work	Results and remarks
43	26	July 1899	Tibia and fibula (lower third, oblique)	3 months	8 months	As no union had occurred a month after admission an operation was performed the ends of the tibia being resected and fixed in position by means of a plate with screws which was removed a month later Result very satisfactory the patient is working as before and can go up and down stairs *easily* the movements of the ankle are free
44	21	August, 1899	Tibia and fibula at junction of middle with lower third	8 weeks	6 "	Patient was admitted in first instance on May 1st and as no union occurred he was re-admitted on August 5th the ends of the bone were exposed and screwed Utility of the limb was perfect He has resumed his former work (bargeman)
45	16	November, 1899	Tibia and fibula (lower third oblique and compound)	3 months.	4 "	When the patient was brought to hospital the lower end of the upper fragment was projecting through his trousers Operation was performed on the same day, the ends of the tibia being united with wire The result is very satisfactory, the outline of the bone being good He can walk and run as well as before
46	27	"	Pott s	1 month	3 "	Patient as before (coal heaver) the movements of the ankle are free Some thickening of external malleolus is present Doubtful if true Pott s fracture
47	33	December, 1899	Tibia and fibula (lower third)	1 "	7 ,	Patient has resumed his former work (carter) No obvious *deformity is present* He walks well
48	42	January 1900	Tibia about the middle	50 days	5 "	Patient working as before (dock labourer) He can go upstairs without pain *His leg as useful as before*
49	38	February, 1900	Pott s	38 "	9 ,	Much thickening of external malleolus is present Patient is working as before (labourer), but not yet full time as the ankle swells and is painful (January, 1901)
50	56	,	Tibia and fibula (lower third, oblique)	2½ months	8 "	Much callus exists at the seat of the fracture and the leg is bent slightly outwards Patient is working as before (labourer), but he cannot go upstairs without pain (January 1901)
51	24	March 1900	Tibia and fibula (lower third, oblique)	6 weeks	7 "	There is marked projection of the lower end of the upper fragment The patient walks well and the leg is quite useful, but the leg and ankle swell at night (January 1901)
52	50		Pott s	1 month	3	Patient working as before (coal heaver) Some flatfoot and pain in leg and foot are present after a day s work (January, 1901)
53	55	May 1900	Dislocation of astragalus and fractured fibula	5 weeks	6 "	The astragalus was reduced under chloroform In January 1901 the general appearance of the foot was normal and movement of the ankle was good The patient was working well and could work as before, but slack time (labourer)
54	44	"	Tibia and fibula (lower third oblique)	65 days	Not yet able to work (13/1/01)	Patient was a heavy man The fracture was a bad one with much swelling and bruising A large bulla formed He had been drinking Slight delirium tremens was present In January, 1901, he was walking with a stick There were considerable swelling of the leg and much thickening at the seat of the fracture The movements of the ankle were impaired
55	23	June 1900	Pott s	4 weeks	3 months	Patient working as before (labourer) Some thickening of external malleolus is present
56	37	July 1900	Pott s	15 days	10 weeks	Patient working as before (waterman) There is thickening of the external and also of the internal malleolus The position of the foot is good and he walks well
57	42	"	Tibia and fibula (lower third oblique)	5 weeks	Not yet able to work. (19/6/01)	The lower end of the upper fragment projects inwards Considerable callus is present The ankle is painful and swells at night The patient walks with difficulty
58	32	August 1900	Pott s	25 days	Not yet able to work. (20/1/01)	Patient cannot resume former work as dock labourer He walks badly and suffers much pain in ankle which swells at night He cannot go upstairs A month ago he bought a small cart and tries to earn a living (January, 1901)
59	48	,	Tibia (about middle)	27 ,	8 weeks.	Patient working as usual (labourer) Considerable callus is present, which, however, is well above the tendons
60	39	"	Tibia and fibula (lower third oblique)	38	Not yet able to work (17/2/01)	Patient is a boiler-maker The outline of the limb is fairly good but the lower end of the upper fragment projects inwards The foot and leg swell at night time He walks with difficulty
61	51	October 1900	Tibia and fibula (lower third)	5 weeks	3 months	Patient walking with a limp (January 1901) but gets about fairly well without any support There is still some swelling at the seat of the fracture She cannot get her boot on
62	32	November 1900	Tibia (about middle)	4 ,	2 "	Patient has resumed his former work (water inspector) The result is perfect as regards function Marked callus is present at the seat of the fracture which however, is well above the tendons
63	45	December 1900	Tibia (middle and also lower third)	6 ,	11 ,	The seat of the double fracture is distinct Much callus is present The outline of the limb is good. The patient walks as well as ever and has resumed his former work (dock labourer)
64	17	January, 1901	Tibia and fibula (about middle)	4	8 "	Patient walked too soon after his discharge and the tibia bent forward. He was re-admitted in April 1901 and was operated upon by Mr Harrison the end of the bone being screwed The final result is excellent as regards function of the limb which is as useful as ever There is much callus which however is well above the tendons He has resumed his former work (labourer)
65	36	March 1901	Tibia and fibula (lower third, oblique)	10 ,	9 ,	In May 1902, the patient had been walking for about five months Now there is considerable limp the heel is drawn up and she has to wear cork inside her boot The foot and ankle are swollen The seat of the fracture is distinct the lower end of the upper fragment projecting inwards

TABLE SHOWING THE ULTIMATE RESULTS IN 76 CASES OF FRACTURE OF THE TIBIA AND FIBULA—(*Continued*).

No	Age in years.	Date of admission to hospital	Fracture.	Length of stay in hospital	Period off work	Result and remarks
66	36	April, 1901.	Tibia (about middle)	2 weeks.	1 month	The seat of the fracture is distinct. The patient is walking with a slight limp Considering how early she walked the result is good (May 1902)
67	51		Tibia and fibula (lower third oblique).	8 "	7 months	As the fracture was oblique and x-ray photograph showed bad position the operation was performed on April 24th, 1901. The ends of the bone were exposed and screwed. The result is very satisfactory The patient walks well and has resumed his former work (labourer)
68	32	"	Tibia and fibula	4	3	The lower end of the upper fragment projects. The patient has a useful leg and walks with a slight limp. Pains are present in the leg and foot. The ankle swells at night (May 1902)
69	30	May 1901	Tibia and fibula, (lower third oblique)	6	3 "	The position of the fragments is unsatisfactory, but the patient declined operation On July 14th 1902, the patient was walking well and without limp or pain; the movements of the ankle were free The seat of the fracture was distinct and marked. The bone end of the upper fragment projected inwards There was a considerable amount of callus The leg for all ordinary purposes was as good as it was before the accident
70	14	"	Tibia and fibula (long and spiral shaped fractures)	9	7	While the patient was in hospital much swelling of the leg was present and it was feared that the result would not be good though the position of the fragments as shown by an x ray photograph was fairly satisfactory In May 1902, the leg was still slightly swollen but he walked well and could run without pain or limp
71	35		Internal malleolus.	5 "	5	There was marked thickening of the internal malleolus The results were very satisfactory In May 1902 the patient was working as before (labourer)
72	35	June, 1901	Tibia and fibula (lower third oblique)	6	8 "	Patient walks with a marked limp and is not able to do heavy work, as the leg is weak and the ankle is painful. Getting upstairs is difficult The lower end of the upper fragment projects (May 1902)
73	16	July 1901.	Tibia, just below the middle (transverse).	7	4½	Patient working as before (engine-cleaner) and the limb is as useful as ever There is not much callus, which is above the tendons (May, 1902)
74	32		Tibia (lower one-fourth oblique)	19 days.	6	Patient walks well and without a limp The limb quite useful for ordinary purposes but he cannot run He has resumed his former work as a groom The lower end of upper fragment projects inwards The leg swells after long standing and some pain is present in the sole of the foot (June 1902)
75	25	November 1901	Internal malleolus.	6 weeks	3	Patient working as before (carter) He suffers no pain or inconvenience from the fracture (May 1902)
76	19	December 1901	Tibia and fibula, at the junction of the middle with the lower third.	5	6 "	Much callus is present at the seat of the fracture and the lower end of the upper fragment projects inwards He walks well and without any limp and says that his leg is quite strong and useful. He has resumed his former work of stage-porter

position a forced one and uncomfortable. A forced one for the reason which Mr Lane was one of the first to point out—namely that when a person is lying on his back the natural tendency is for the feet and legs to rotate slightly outwards. What then happens when we apply this splint for a fractured tibia and fibula? The foot is securely fixed to the [illegible] and prevented from rotating outwards [illegible] being so securel [illegible] so the broken enc [illegible] Nor is this all, [illegible] heel in contact w [illegible] ult to keep it t [illegible] nt on the streto [illegible] ments is necess [illegible] es we have the [illegible] t then endeavour to imitate the natural position of rest as far as possible?

The form of splint which I have found most generally useful for fractures of the tibia and fibula, including cases of Pott's fracture, is a back splint with a foot-piece, but this foot piece instead of being vertical is inclined outwards to an angle of 70° and with the same inclination forwards. A splint so shaped permits of the foot and leg being fixed in the natural position of rest. The patient is more comfortable in a splint of this description and as no endeavour is made to force the foot into an unnatural vertical position there is much less tendency to the formation of a sore over the heel Moreover, the tendo Achillis not being in a state of passive tension (as is the case when the vertical foot piece is used) the tendency to overriding of the fragments is lessened

The leg piece of this splint should be of such a length as to permit of the knee being bent and, after the applications of side splints, to allow the leg and splint to be swung from a cradle. When the fractured bone has firmly united say at the end of four weeks, movements of the ankle and knee joints should be encouraged and massage practised if available The mistake usually made is keeping the injured limb in a state of immobility for too long a time If the fracture has been an oblique one it should be remembered that the newly formed callus will have to bear the strain of the body weight, and consequently will be apt to "give" if the patient rests the full weight of his body on the injured limb before the end of the third month

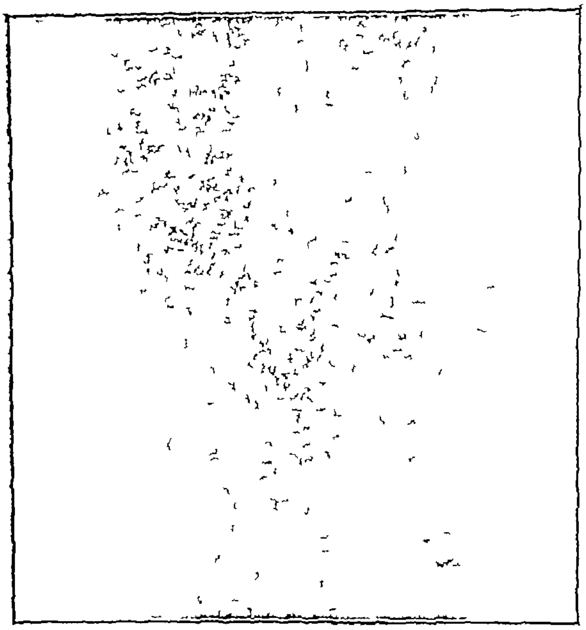
But whatever form of splinting is employed I feel sure that in a certain proportion of cases of simple fracture of the tibia, more especially when the fracture involves the lower one-third of the bone and is of the oblique or spiral character try as one will, even with the patient under the influence of an anæsthetic, one will fail to obtain a satisfactory apposition of the broken ends of the bone because it is practically impossible by splints alone to get the broken ends in accurate position and to keep them there. If anyone doubts the accuracy of this statement let him have an x ray photograph taken of such a fracture after the splint has been applied I wish this was much more frequently done than it is at present, and when there are facilities for doing so I would suggest that it be always done in doubtful cases

What is it that prevents the replacement of the fragments? After some experience in operating upon these cases, I feel sure that Mr Lane is correct when he says:

"Spasmodic muscular contraction affords a very slight and transitory obstacle to the replacement It can be measured and placed in abeyance for the time being by putting the patient under an anæsthetic In simple oblique fractures the chief obstacle to replacement of the fragments in accurate apposition is hæmorrhage into and inflammation of, the soft parts." And I would add another factor occasionally met with—namely, the piercing of adjacent muscles and fascia by the sharp ends of the broken bone.

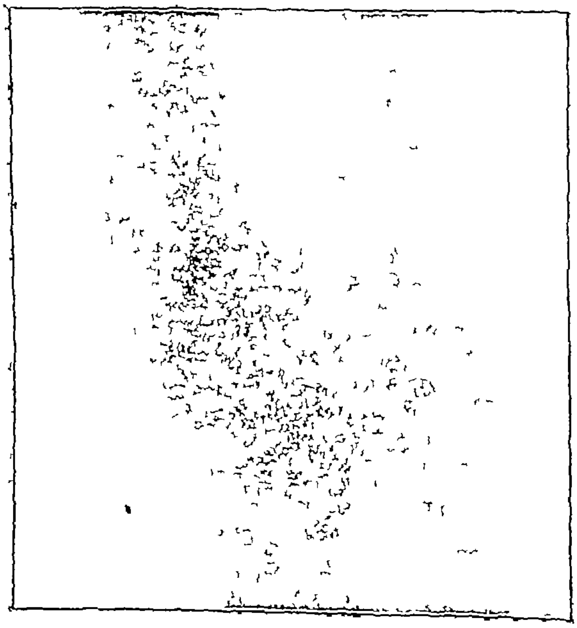
I take it that all surgeons are agreed that the more completely a fracture is reduced the better, and there can, I think, be no doubt that if "accurate apposition" of the broken ends of the bone is essential in order to restore the complete and perfect utility of the injured limb the logical conclusion must be to cut down upon, and to expose, the broken ends in the vast majority of cases. But is such a procedure either necessary or justifiable? For my own part I have no hesitation in saying, Certainly not. Any surgeon who has really interested himself, not only in the *immediate* treatment of fractures, but who has also followed *his cases* to a conclusion, must realise that although it is practically impossible, for reasons which I have mentioned, *to obtain by* any means short of operative interference accurate apposition of the broken ends of the bone, still, clinically, the results in many such cases have been perfect even when the line of fracture has been of some obliquity. At the same time I am sure, speaking as a hospital surgeon with a labouring man as a patient, that there is a considerable number of cases in which operative treatment is not only justifiable but urgently called for.

FIG 1 (CASE 76)



Simple fracture about the middle of the tibia and fibula Skiagram taken at the time of the accident.

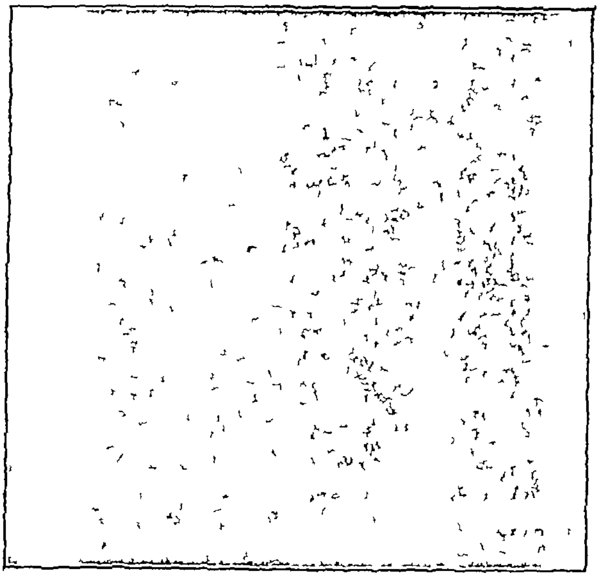
FIG 1A



After recovery No operation useful limb

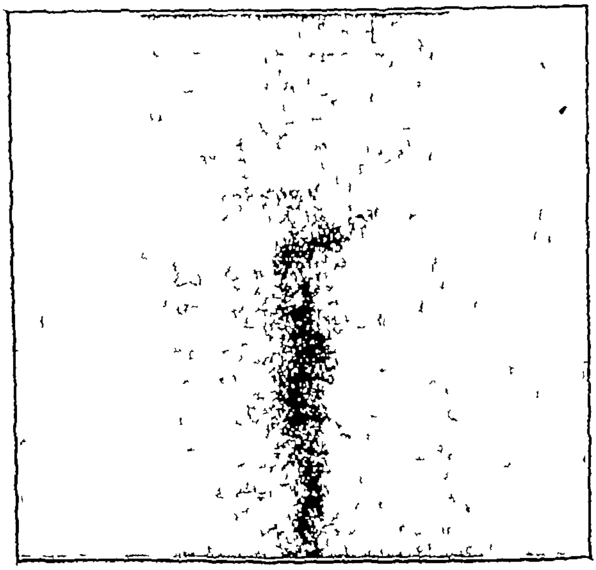
In deciding for or against an operation in any individual case the employment of the patient and the position and character of the fracture as determined by the x rays should be carefully considered. As regards the position of the fracture, if it is situated in the upper two-thirds of the tibia—namely, that part of the bone above the position of the tendons—operative interference is seldom called for. If on the other hand, the lower one-third of the bone is involved and the fracture is oblique or spiral shaped, I would suggest that if after the fracture has "set" one half or more of the fractured surfaces are in contact, and provided that there is no rotatory displacement, an operation is

FIG 2 (CASE 66)



Before operation

FIG 2A.



After operation.

not called for in the majority of such cases but if these conditions cannot be obtained the broken ends should be exposed and fixed securely and accurately together Though undoubtedly there are cases in which the x rays, if they are to be trusted, clearly demonstrate not only an oblique fracture involving the lower one third of the tibia but also show that considerably less than one half of the fractured surfaces are in contact, and yet the patients have recovered with the utility of the limb restored, still I am convinced that such recoveries are the exception I have a photograph of a fracture which is an excellent illustration of this point. (See Fig 1 and 1A.)

In cases of a doubtful nature the employment of the patient will probably turn the balance for or against an operation. A leg with its utility slightly impaired might still serve all the purposes of a tailor but the same degree of deficiency would render it useless to a postman. At the same time it would be idle to deny that there are certain risks in operating for although it would appear to be a simple enough procedure, judging from the x ray photograph, still the actual operation is often one of considerable difficulty A very free incision is advisable and the chances of sepsis will be considerably diminished if the operator and his assistant keep their fingers from contact with the wound. I do not propose to deal with compound fractures of the tibia, but cannot refrain from mentioning that the results are frequently much better than after a simple fracture no doubt owing to the wound relieving the soft parts of extravasated blood and inflammatory products. Further the practice, which I presume is now universal, of enlarging the wound for cleansing purposes permits of a view of the actual position of the bones—strong arguments, by the way in favour of operating for simple fracture. (See Fig 2 and 2A.)

Passing now to the consideration of the cases of so-called Pott s fracture I say 'so-called advisedly for in many cases that are diagnosed as Pott s fracture the injury sustained is by no means so severe as at all to answer to the *original description of Mr Percival Pott.* And this criticism would probably apply to several of the cases in the appended table Here, again I maintain that the x rays should be frequently employed, for in a few hours the swelling of the foot and ankle makes it practically impossible correctly to estimate by ordinary means the exact nature of the injury and the relative position of the broken bones.

From x ray photographs which I have had taken of Pott s fracture I would say that the usual defect remaining after reduction is a slight displacement outwards and backwards The form of splint which I have already suggested will be found especially useful for this class of fracture, for if the foot is forced into a vertical position the tension on the tendo Achillis will tend to exaggerate the already slight displacement of the foot backwards. When a fracture is close to a joint early passive movement and massage are of great importance, and after a Pott s fracture this line of treatment should be adopted at the end of the third week. I have never considered it necessary to operate upon these cases and feel sure that the indications for doing so must be very exceptional.

It only remains for me to say in conclusion, that I have *personally investigated the after results in every case here* recorded, which although a somewhat troublesome procedure is, I believe, infinitely better than collecting the mere general impressions of others, for general impressions are apt to be somewhat misleading, and if my small effort will only induce surgeons to take more interest in their cases of fractures, and so bring this branch of surgery more in a line with the general surgical advance, I shall be satisfied

Liverpool.

An Unruly Workhouse Inmate.—At the meeting of the Warminster board of guardians held on August 25th a discussion arose about a workhouse inmate who had assaulted the master and porter and had threatened " to swing for the medical officer " The man had been sentenced to four months imprisonment, but as he was destitute the chairman said that he would probably return to the workhouse at the expiration of his sentence. It was decided to write to the Local Government Board asking if the Board would sanction any exceptional treatment in regard to the man, as the guardians felt that they must protect their officers whilst discharging their duties

---

THE CHOICE OF AN ANÆSTHETIC FOR SHORT OPERATIONS UPON THE THROAT AND NOSE[1]

By J Henry Chaldecott L.R C.P Lond,
F F.P S. Glasg.

Anæsthetist to the Metropolitan Throat and Ear Hospital and
Italian Hospital; Late Assistant Anæsthetist to the
Central London Throat Nose, and Ear Hospital.

By short operations I mean those which can be performed during the time which elapses between the removal of the anæsthetist s mask and the patient s return to consciousness. The most common of these are tonsillotomy and the removal of adenoids posterior and anterior turbinectomy, removal of nasal spurs and polypi and draining the antrum of Highmore through the alveolus. The anæsthetic agents which we have to choose from are chloroform A.C E and C E. mixture nitrous oxide, nitrous oxide and oxygen, nitrous oxide and ether ether, and chloride of ethyl.

Tonsillotomy and Removal of Adenoids.

The enormous number of these operations now performed renders the choice of a suitable anæsthetic a very important matter The operation *per se* entails no immediate risk to life, and one can hardly conceive the possibility of a patient dying on the table or in the chair if operated upon without an anæsthetic. It follows then, that any fatalities which have occurred have been caused by the anæsthetic employed and so far as I have been able to ascertain the anæsthetic has in every recorded case been chloroform or some mixture containing *chloroform. I have collected a list of more than* 50 recorded deaths under chloroform given for this operation including children and adults cases in which the chloroform was given by specialists in anæsthetics and cases *in which it was administered by general practitioners and* house surgeons cases of death at all stages of the procedure, before the commencement of the operation, during the operation and after its completion. Now this list lays no claims to being exhaustive and could probably be largely increased. What, then, is the obvious deduction? That here we have an operation which ought to be and is in itself absolutely free from immediate danger perverted by the use of chloroform into one of the most immediately deadly of any in the long list of surgical operations. Is there any one surgical operation—major or minor—which can claim such a record of deaths upon the table? I doubt it. Could any or all of these fatalities have been avoided? I think so, and how? by avoiding the use of chloroform. In 1897 in a paper read before the British Medical Association by Dr Waller the author remarked I am greatly astonished that, in the face of the clinical experience of the last 50 years, chloroform should still be employed for the purposes of minor surgery " These words were spoken in 1897 and since then more than 30 *recorded* deaths from chloroform have taken place during adenoid operations only

Now what was the cause of death in these cases? In a *small percentage of the cases blood was found post mortem* in the larynx trachea, and bronchi, death having been apparently due to this cause but in the majority no such cause was discovered and the patients had apparently succumbed to an overdose of chloroform and it is easy to appreciate, firstly that adenoid subjects whose intake of oxygen is already insufficient, are very likely subjects to be poisoned by chloroform and secondly that a gasping and coughing patient, with perhaps his mouth half full of blood, is quite likely if the chloroform is continued during the operation to get a very intermittent supply—none one inspiration and perhaps a deadly dose the next. With reference to those who died from blood in the air passages we may be told that these accidents would not have happened if the chloroform had not been pushed far enough to abolish the cough reflex. Quite so but it is by no means easy in all cases to know exactly when anæsthesia has arrived at that particular point, and with chloroform one is also met by the difficulty that the patient may pass into deeper anæsthesia after the removal of the mask. I do not dispute this a longer anæsthesia after the removal of the mask can be obtained with chloroform than with any other anæsthetic, but I maintain that in order to obtain that increase of time the drug must be pushed to the extent of abolishing the cough reflex or perilously near it, and that an anæsthesia which stops short of that point has no advantage whatever over ether narcosis and is infinitely more dangerous

---

[1] A paper read at the Metropolitan Throat, Nose and Ear Hospital

What, then, are the alternative methods? Infants aged less than 12 months should be given ether on an open mask. Children from one to four years of age do not take N_2O well, especially if they have large tonsils, but, as a general rule, they take ether without any trouble at all from a Clover's inhaler, with or without the bag, according to the ease with which they go under For children from four to 12 years of age N_2O will generally do, but if when pressed it causes much jactitation and rigidity it is better to give a little ether In adolescents and adults the operation can be done under gas alone in most cases, indeed, a rapid operator will frequently remove in the time allowed by N_2O anæsthesia tonsils, adenoids, and the posterior ends of the inferior turbinals What a rapid operator will do under gas only an average operator will do easily under gas and ether

Gas and oxygen is perhaps *slightly better than gas or gas* and air, but for these operations the apparatus is rather inconvenient, and as a matter of fact, we find that gas or gas and ether meet our demands The purified chloride of ethyl used as a general anæsthetic is still under trial, but from the results I have had in about 80 cases I doubt if it has any advantage over ether, and it is certainly less trustworthy and more tedious to administer

What do the critics of these methods say? Their first objection is that the operation cannot be satisfactorily and completely done under this form of anæsthesia Now, this method has been in vogue at the Metropolitan Throat, Nose, and Ear Hospital and at the Central London Throat Hospital for 12 years, during which time 20,000 cases have been so operated upon. Is it seriously suggested that the surgeons attached to these two hospitals have not learnt in 12 years whether or not they can clear a naso-pharynx of tonsils and adenoids in the time allowed by a gas or gas and ether anæsthesia? If at these hospitals these operations were habitually only half done would there not be an ever-increasing back flow of recurring cases? As a matter of fact, the percentage of recurrences is very small and certainly not greater than that of cases done under chloroform elsewhere The second objection which is raised is that gas and gas and ether cause more hæmorrhage than chloroform Even supposing that they do so, unless it can be shown that they cause *dangerous* hæmorrhage the objection ought not to be taken into account against the risk to life which I have shown is entailed by the employment of chloroform, but, personally, I believe the objection to be purely fanciful. I can only say that amongst the several thousands of these operations which I have seen and assisted at I have never seen a case of alarming or even of serious hæmorrhage We are told that while chloroform kills on the table, ether kills by its after effects, and with prolonged administrations this is doubtless sometimes true, but the objection does not, of course, apply to short inhalations of ether such as are employed for the operations in question.

Gag—The best gag for these cases is certainly Doyen's, and it should be applied before the administration of the anæsthetic.

Position.—For gas or gas and oxygen the sitting position is very much the best For ether or gas and ether some surgeons prefer the recumbent position, and it is not a matter of much importance From an anæsthetist's point of view I prefer the sitting position as being more cleanly and as obviating the necessity of using mops or sponges

The other operations on the list can all be done under gas, gas and oxygen, or gas and ether, and there is never any necessity for the use of chloroform.

In conclusion I should like to explain that I do not suggest that the methods which I here advocate are confined to the two hospitals named, I only quote them because I have personal experience of their work and access to their records. Nor do I wish to be misunderstood in my attitude towards chloroform, which in suitable cases I regard as *facile princeps* of anæsthetics The points that I wish to emphasise are (1) chloroform has been the means of destroying more than 50 lives during adenoid operations and cannot, therefore, be regarded as other than a *dangerous* anæsthetic in this particular class of case, (2) at least five of these deaths have occurred in the practice of anæsthetists of the highest possible skill and experience, and (3) thousands of these operations are performed every year under gas and gas and ether without a single death and with hardly an anxious moment. In view of these facts, are we justified in subjecting patients to the absolutely unnecessary risk of chloroform anæsthesia? I think decidedly not.

Welbeck-street, W

A CASE OF TRAUMATIC RUPTURE OF THE SPLEEN, REMOVAL FOLLOWED BY EMPYEMA AND RECOVERY

BY EDGAR BEAUMONT, L R C P LOND, M R C S ENG,
SURGEON TO THE NORWOOD COTTAGE HOSPITAL,

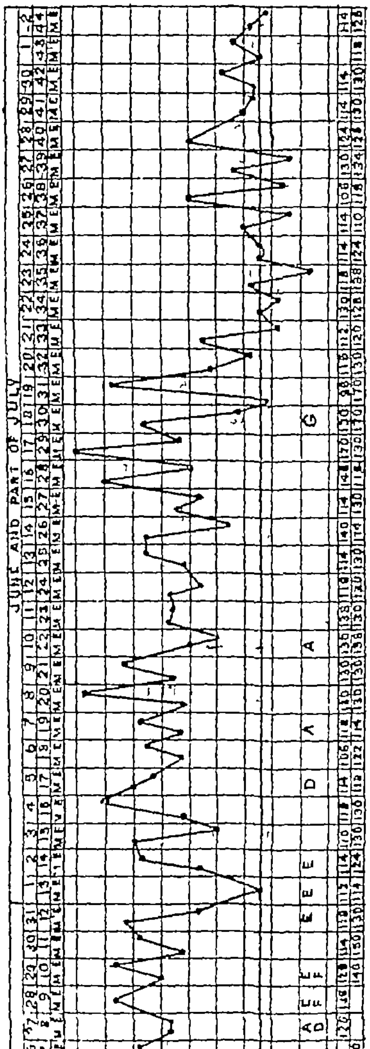
AND

EDWARD HOUSEMAN, M B, B C CANTAB,
LATE HOUSE SURGEON TO ST GEORGE'S HOSPITAL

THE patient was a youth, aged 17 years, who was brought into the Norwood Cottage Hospital on the evening of May 20th, 1902. There was a history of his having fallen from a wagon, one wheel of which passed over his body On examining the youth we found that he was suffering great pain in the left loin There was a bruise over the ninth and tenth ribs in the posterior axillary line of the size of the palm of a man's hand. His temperature was 97·6° F, his respirations were 24, and his pulse was 100 His breathing was not markedly thoracic and there was an absence of rigidity of the abdominal muscles There was no evidence of fractured ribs, but there was dislocation of the acromial end of the clavicle and a fracture across the infra spinous fossa of the scapula with a large hæmatoma under the bone A few hours after admission the boy became very restless and the distension of the abdomen, with loss of liver dulness, brought forcibly to our minds the fact that there was severe abdominal lesion and decided us to open the cavity without delay Chloroform and ether were administered and we were then able to feel distinctly a loose body in the left hypochondrium which we took to be, and which ultimately turned out to be, a portion of the spleen In consequence of the loss of liver dulness we thought it likely that there might be intestinal injury as well, so we decided on a median incision.

We made a free incision in the middle line and on opening the peritoneum found the cavity full of blood clot. In addition there was a welling up of blood, showing that active hæmorrhage was still going on. There was no free gas in the cavity On pressing the hand into the cavity the spleen was instantly felt to be in two pieces, and on finding and holding the vessels between the finger and thumb the hæmorrhage was controlled The spleen was then drawn forward to the surface, the pedicle was clamped, and after separating the tail of the pancreas from the hilum was transfixed, tied, and divided and the spleen removed The abdominal cavity was then flushed with several gallons of hot sterilised water and the abdomen closed There was considerable ecchymosis of the intestines

The patient by this time had become very collapsed, so 15 minims of liquor strychninæ were injected hypodermically before he was removed from the table and hot salt-water injections per rectum with five minims of liquor strychninæ hypodermically were continued every three hours during the night. Next morning we found the patient fairly comfortable, the pulse, which had been 160 after the operation, had come down to 120 He had not vomited, but there was still absence of liver dulness and the patient lay on his back with his knees drawn up He was unconscious and moaned incessantly His temperature was 101 5° He remained in much the same condition until the third day after the operation, when his temperature suddenly shot up to 105° He became violently delirious, restless, and sweated profusely, there was diarrhœa and urine was passed under him, so we decided to dress the wound, which we found apparently healthy The abdomen was *slightly distended but moved* freely and did not seem tender On the sixth day after the operation we found some fluid effused at the base of the left lung, so we aspirated and removed six ounces of decomposing blood with an almost fæcal smell. As there had been no



A Operations first, second, third and fourth B Hypodermic injection of morphia. C, Tepid sponging D Aspiration of fluid E, Injection of anti-streptococcic serum. F Stitches removed. G Irrigation. Temperatures were taken every four hours; only those taken at 10 A.M. and 10 P.M. are shown in this chart.

fracture of ribs at the time of the accident we concluded that this had probably come through the diaphragm from the abdominal cavity and so we decided to explore the subdiaphragmatic region.

With this object we made an incision in the loin from behind forwards, the centre of the incision being over the angle of the eleventh rib We resected the lower ribs and so were enabled without difficulty to examine the stump of the spleen. Not finding any pus we closed the opening On this we concluded that septicæmia was the cause of his high temperature and general condition, so we made an examination of the blood and found streptococci in large numbers. We therefore commenced the hypodermic injection of anti *streptococcic serum and gave him 90 cubic centimetres* with little effect on his temperature and within four hours he developed a very large pleural effusion on the left side only the dulness extending up to the clavicle so we aspirated and withdrew two pints of fluid slightly blood stained and sweet. We continued the injection for four days during which time we used 330 cubic centimetres of the serum On the morning of the fifth day after these injections had been commenced the temperature came down to normal and the patient was quite conscious for the first time for nine days. All the wounds including the hypodermic punctures became about this time septic in spite of antiseptic dressings, so we swabbed the worst of them with pure carbolic acid. After this treatment they cleaned up very much. On June 5th 15 days after the original operation we found signs in the left chest about the angle of the scapula of a localised empyema, so we aspirated and found pus and subsequently resected considerable portions of the seventh and eighth ribs. There was free discharge of pus for several days, but the temperature remained high, reaching 104° and 105° daily The cavity was washed out with a weak solution of lysol and remained sweet but as the temperature remained high we decided to try the effect of the frequent application of pure oxygen through a tube passed into the pleural cavity This treatment was attended by the most satisfactory results. The temperature came down to normal the discharge ceased and a general repair commenced in all the wounds With the exception of the wound leading into the pleural cavity all are now healed this is rapidly closing and the lung is expanding well and filling the cavity The patient is in good general condition eats and sleeps well and spends his time in the garden.

Remarks —The following points are of interest in this case. 1. The absence of collapse and comparative slowness of pulse in so severe an abdominal injury 2. That since the removal of the spleen the pulse has never come below 112, although the patient is now in comparatively good health. 3 We have noticed that since the removal of the spleen there has been marked general enlargement of lymphatic glands with anæmia. 4 The very slight reaction to exceptionally large doses of anti streptococcic serum although to get different strains we obtained it from different sources 5 The extraordinary general and local improvement which took place at once on the application of oxygen to the pleural cavity

Addendum —At this date (Sept. 8th) the patient is perfectly recovered and is to all appearances in as good health as before the accident He is occupied in light gardening &c. His pulse rate still remain however, at from 112 to 120

Clinical Notes

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A PECULIAR CASE OF SCARLATINA HÆMORRHAGICA.

By J DUNCAN HOWE, M R.C.S ENG

FORMERLY ASSISTANT MEDICAL OFFICER, MONSALL FEVER HOSPITAL, MANCHESTER.

THE following are notes on a case similar to the one reported by Dr C D. Boinville in THE LANCET of August 9th, 1902, p 359

The patient, a boy aged six years suffering from necrosis of the right tibia, had been an inmate of the Cheadle

Convalescent Home for six weeks On Sept 8th, 1885, an erythematous blush was observed around the wound on the right leg On the 13th it was elicited that he had been restless during the night and on waking in the morning the trunk and limbs were covered with a red rash There was no sore throat, rigor, or vomiting The temperature was 99° F. On the morning of the 14th the patient was admitted into the Monsall Fever Hospital. The temperature then was 103° and the pulse was 132. The body and limbs were covered with a brilliant red, fine punctate rash and the cheeks were very red, but there was no cervical glandular enlargement The right tonsil was ulcerated and there was a small yellow patch on it, the left tonsil was enlarged and injected and the fauces and conjunctivæ injected. In the evening the temperature was 99·2° and the pulse was 116 The patient progressed favourably as regarded the scarlet fever Desquamation began on the 19th and continued normally Nothing further was observed or reported about the case until Oct 7th, the twenty fifth day of the illness, when there was difficulty in micturition. On examination there was found œdema of the skin of the penis and prepuce, but not of the scrotum. It was relieved by acupuncture and there was no further trouble On the 8th a large square purple patch, two inches by two inches, surrounded by a light-red halo, was observed on the inner side of the calf of the left leg On the 9th a similar patch appeared on the outer side of the right thigh It was of about the size of the palm of the hand. At 5 30 P M it had extended upwards as far as the groin and downwards to the knee, and encircled the whole thigh and was spreading to the buttock. The parts implicated, which were tense, smooth, and shining, did not pit on pressure but were hard There was no pain or tenderness The patch on the right leg had not spread since the previous day The cuticle over it was raised and the subjacent part looked like a piece of raw liver There was no œdema of the penis or the scrotum. The rest of the body presented a blanched appearance. Treatment had no effect in stopping the progress of the hæmorrhage There were no hæmorrhages from the interior of the body The patient died quietly on the morning of Oct. 10th.

Preston

TWO CASES OF FOREIGN BODIES SWALLOWED AND THEIR TREATMENT

BY H. W BOREHAM, M B EDIN

THE first of these cases was that of a woman who had swallowed three false teeth with their plate, which when *in situ* was attached to the molars on either side of the upper jaw by means of the ordinary wire arrangements One of these latter had been broken, leaving a sharp point about a quarter of an inch long directed straight outwards from the plate. The woman was in a great state of nervousness and complained of considerable pain in the epigastrium. After the administration of 20 grains of bromide of ammonium she was given bran and coarse porridge with small pieces of thread in large quantities, allowing the minimum amount of fluid The pain soon left her and in the course of two days she passed without any pain the plate which was found to be encased in the thread and bran, forming a solid mass

The second case was that of a man who had swallowed a pin He was treated in the same manner with an equally good result.

In my opinion it is very important that in such cases as little fluid as possible should be allowed during the first two days, and that the bowels should be kept somewhat confined, by the use of opium if necessary, until the foreign body has been passed

Swindon.

A METHOD OF TREATING TRAUMATIC TETANUS

BY DR. S ZLOTOWSKI.

IN 1877, when holding the position of chief of the surgical department of the Imperial Ottoman Military Hospital, Gumush Son, at Constantinople, I had occasion to remove the terminal phalanx of the index finger of a soldier On the third day after the operation trismus set in and on the fourth day there was opisthotonos with violent spasms No benefit being derived from treatment on the ordinary lines I had recourse to a method which has not, so far as I know, been mentioned in medical literature Attached to the hospital there was a Turkish bath which was being used day and night The patient, in a state of universal rigidity, having been taken there was kept lying on a hot marble slab and every four hours was put into a hot bath for 30 minutes This treatment succeeded admirably The spasms ceased, the breathing became more free, and the tetanic symptoms diminished. Before the expiry of the first six days the patient felt comparatively well, the trismus and opisthotonos almost disappeared, he could walk about and even take solid food, and he was very averse to persevere with the treatment which I was intending to continue for at least a day or two longer Disobeying orders he made his way out of the bath premises to another part of the hospital, but had hardly arrived there when the tetanic symptoms returned with great severity I therefore had him carried back to the bath and resumed the treatment. The symptoms immediately improved and after 14 more days in the Turkish bath and 24 days' treatment in the wards he was able to return to his regiment quite recovered The last patient whom I have treated for tetanus was a woman, about 35 years old, who had run a rusty nail into the sole of her foot As there was no Turkish bath at hand I had a stove put into a room the temperature of which was kept day and night at 35° R. In this room she had a hot bath every three hours, remaining in the bath for 30 minutes After 14 days' treatment in this heated room she was entirely cured.

This method used by me can be applied in any house or even hut The temperature of the room is kept between 32° and 35° R. (between 104° and 111° F) and every three hours the patient has a hot bath of 30 minutes' duration. Morphine injections along the vertebral column are used for the purpose of soothing pain. The result of this treatment, which must be continued for at least 15 days, will always, I think, be satisfactory

BIRMINGHAM GENERAL HOSPITAL

A CASE OF HÆMATURIA OF MANY YEARS' DURATION DUE TO VILLOUS PAPILLOMA OF THE RENAL PELVIS, NEPHRECTOMY

(Under the care of Mr GEORGE HEATON and Mr LEONARD PARKER GAMGEE.)

VILLOUS papillomata of the pelvis of the kidney are extremely rare, but histologically they are indistinguishable from the villous growths of the bladder They may affect both kidneys,[1] and a case has been recorded by Murchison[2] in which not only were both kidneys affected by these papillomata but a similar growth was found in the bladder at the orifice of each ureter

A man, aged 48 years, while at work one day nine and a half years ago felt "something go in his left side" On the next day he noticed blood in his urine and for two days afterwards the hæmaturia was very severe After this there was a complete absence of symptoms for six months, but at the end of that time the hæmaturia returned and the patient was admitted into a hospital near Birmingham. There the left kidney was exposed by the lumbar operation but with a negative result. For some time after this the attacks of hæmaturia recurred at intervals of about six months, and eight years ago, during an especially severe attack, the man was admitted into the Birmingham General Hospital under the care of Mr Heaton, and as the bladder was distended up to the umbilicus with blood clot suprapubic cystotomy was performed but no source of bleeding could be found in the bladder. There was no hæmaturia for three months after this but then the attacks began to increase in frequency and the patient was admitted into the same hospital as on the first occasion and his right kidney was explored but also with a negative result. The hæmaturia continued and four years ago the left kidney was again explored in the same hospital but with a similar result.

---

[1] J Bland Sutton: Tumours, Innocent and Malignant second edition, p 225

[2] Transactions of the Pathological Society of London, vol xxi, p 241

The patient was readmitted into the Birmingham General Hospital two and a half years ago and the bladder was examined with the cystoscope but no source of the bleeding could be found. Since that time he had had almost constant severe pain in the left loin and had passed blood every day. On Jan. 1st, 1902, he was again admitted into the Birmingham General Hospital. He was very anæmic, was passing a large quantity of blood each time he micturated and on bimanual examination his left kidney was felt to be much enlarged. He also complained of constant aching pain in the region of the left kidney. As previous explorations of the kidney had been without result it was decided that the best course to adopt would be to perform lumbar nephrectomy. Accordingly on Jan. 10th, this was done by Mr Gamgee, the operation proving to be difficult owing to the very dense adhesions resulting from the two previous operations. The patient made an uneventful recovery and is at the present time in good health and free from hæmaturia.

The kidney after removal was found to be of about twice the normal size of the organ. The renal pelvis was dilated and completely filled with a diffuse villous growth which was growing from the whole of the lining wall of the pelvis there being apparently no part of the wall free from growth which however did not extend down the ureter. The kidney substance had completely disappeared only a fibrous walled sac remaining. The inner lining of the sac wall was over about two-thirds of its area covered with villous growth which did not fill the sac to the same extent that the pelvis was filled. On microscopic examination the growth was found to be a non malignant villous papilloma.

Remarks by Mr GAMGEE.—The existence of a villous papilloma in the pelvis of the kidney gives rise, in the first instance, to symptoms strikingly like those caused by the presence of a similar tumour in the bladder—namely intermittent profuse hæmaturia with intervals of freedom from symptoms. In this case at the time of operation the enlargement of the kidney had given the first definite information as to the source of the bleeding and it was felt that nephrectomy and not simply another exploration, would be the best treatment. Notwithstanding that the growth had been in existence for such a long time, the interior of the ureter was apparently free from growth though it is a well known fact that such a growth occurring in the pelvis of the kidney may extend down the ureter into the bladder. The irritation caused by the presence of a calculus may give rise to a villous papilloma in the renal pelvis, but in this instance it does not seem possible to assign any direct cause. The case came under my care owing to the absence through illness of Mr Heaton to whom I am indebted for permission to use the notes relating to the past history of the patient and for valuable advice concerning the treatment of the case.

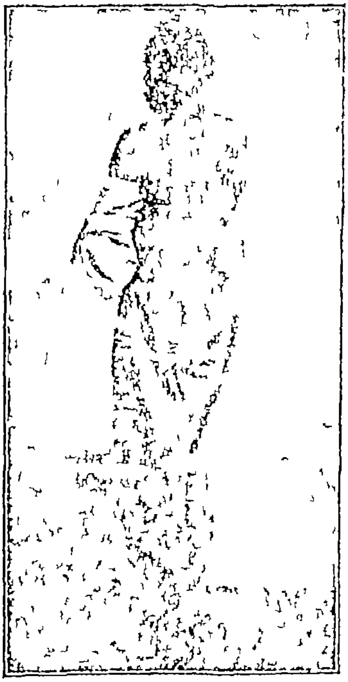
CIVIL HOSPITAL, HALFA, SOUDAN

A CASE OF LUMBAR HERNIA

(Under the care of Mr A. WEBB JONES.)

LUMBAR hernia is a hernia through or in the neighbourhood of the triangle of Petit. The size of this triangle varies greatly in different persons. It consists in an interval left between the latissimus dorsi and the external oblique muscles and sometimes these overlap at their attachment to the iliac crest, so that then no triangle of Petit exists. In many cases of lumbar hernia an abscess has weakened the abdominal wall at this spot in others there is a clear history of local injury. These herniæ have a great tendency to strangulation[1] and in the first case of which we have any record the patient died from the strangulation in 1731.[2] Ravaton[3] in 1738 operated successfully on a strangulated lumbar hernia. Mr Edmund Owen's[4] case was the first in which a radical cure was performed of a hernia of this form and below is recorded a very successful radical cure of a large lumbar hernia.

In a fairly typical case of lumbar hernia the patient was a well-developed male Soudanese, aged about 45 years. He had noticed the swelling for some four or five years and had lately had considerable trouble from local pain and tenderness, with constipation and dyspepsia. The patient could not recall any special blow or strain to which one might attribute the protrusion but of course any such details from a native of his mental calibre would be of little value. For some days previous to the operation his evening temperature ranged between 99° and 100° F. On examination the right lumbar region presented a large fluctuating tumour roughly oval in shape but of slightly irregular outline. It extended from the level of the iliac crest inwards and upwards towards the spine and overlapped the lower three or four ribs. The mass gave one the impression that it was to a great extent composed of fat, but on reduction—which was easily effected through Petit's triangle—a distinct gurgle was to be felt. The impulse on coughing was very well marked. Over the site of Petit's triangle was a broad scar about two inches long. Mr Jones was of opinion that this was the result of a mere superficial cut and had no causal relation to the hernia. (It should be mentioned that the habit of making *skin cuts with a razor either for* cosmetic or medicinal effect is very common amongst the



Lumbar hernia.

[4] THE LANCET, May [illegible], p. [illegible]

Soudanese.) In the left lumbar region there was a slight undue fulness, apparently consisting of fat (perhaps subperitoneal in origin and the forerunner of a hernia), but this gave rise to no symptoms The patient also presented a left inguinal hernia of moderate dimensions.

An operation with a view to a radical cure was commenced by an oblique incision downwards and forwards over the site of the triangle After retracting the edges of the external oblique and latissimus dorsi the lumbar fascia was incised. Here a large lobulated mass of adipose tissue presented. The depths of the opening appeared to be divided, so to say, into an upper and lower division by some fibrous bands, above and below which portions of the fatty tissue protruded. Traction on this tissue brought into the wound the ascending colon, which appeared somewhat dilated and thickened After removing the fat and reducing the colon, the edges of the latissimus dorsi and external oblique were united with silkworm gut and the wound was closed. Primary union was obtained and recovery was uneventful

Remarks by Mr. Jones —Herniæ in the region of Petit's triangle, other than those following abscess, are so uncommon that an account of a fresh case may prove of interest. Looking at the somewhat imperfect records of 25 old cases[5] one is able to generalise on the common features of this rare condition With regard to etiology the sexes are almost equally represented, whilst the majority of the herniæ appear for the first time at middle age Three of the 25 cases occurred in infants, but one of these followed an old psoas abscess By far the gravest characteristic, however, of this variety of hernia is its very marked tendency to produce symptoms of local pain, constipation, or even strangulation. Of the 25 cases referred to above no less than four became strangulated, five are said to have been from time to time the cause of vomiting, colic, or constipation, whilst six only are stated definitely to have given no trouble , the rest are without details One case was bilateral and associated with an inguinal hernia. In two instances the diagnosis was at fault and the bowel was damaged, the surgeon being under the impression that he was incising an abscess

The question of the existence or non existence of a sac in these cases is a matter of great interest. In Dr G H Hume's[6] case (operated on for strangulation) a sac is mentioned, but no post-mortem examination was made In Mr E Owen's[7] case (radical cure in a small child who developed a hernia after an old psoas abscess) the point was not investigated. In the case dissected by Mr J Hutchinson, jun ,[8] no sac was discovered, but he suggests that the elasticity of the peritoneum together with its loose attachment in this region might allow of some protrusion through the opening with intra abdominal strain, the peritoneum recoiling, with the reduction of the hernia to resume its normal position. I am of opinion that probably such may have been the case to some extent in my own patient. The protrusion of the fatty tissue and colon would doubtless account for a large bulk of the tumour seen on external examination, but I think that a residue would still remain unaccounted for The fibrous bands crossing the depths of the triangle are also worthy of note. Dr Hume, in his case of strangulation attributes the constricting agency to similar structures However, his case did not absolutely correspond to the anatomical site of Petit's triangle, so the parallel may not be insisted on too closely

Vaccination Fees —At the meeting of the Hambledon (Surrey) board of guardians held on Sept, 4th the vaccination committee recommended that fresh contracts should be made for public vaccinators and that the fees should be modified in accordance with the following scale— namely, that a fee of 2*s* 6*d* be paid for the revaccination of all persons at boarding schools, hotels, boarding houses, and all similar public institutions and places of business The clerk said that many of the people who were vaccinated at their homes might well go to the surgery to be vaccinated for 2*s* 6*d* The recommendation was adopted The clerk suggested that the scale should be submitted to the public vaccinators for their observations before sending to the Local Government Board. This course was adopted

Reviews and Notices of Books.

Diseases of the Intestines By John C Hemmeter, M D , Philos D , Professor in the Medical Department of the University of Maryland , Consultant to the University Hospital and Director of the Clinical Laboratory In Two Volumes Volume I With many Original Illustrations London Rebman, Limited. Pp 742. Price 50*s* (complete work)

This work promises to be one of the most complete monographs on diseases of the intestines yet published. The first volume is concerned with the anatomy and physiology of the intestines, the chief bacteria which infect the tract, methods of diagnosis, therapy and materia medica of intestinal diseases, the symptomatology of these affections, and chapters on intestinal indigestion, enteritis, dysentery, ulcers of the intestine, and intestinal neoplasms Three chapters of the work have been written by associate professors in the University of Maryland. These deal principally with the more scientific, as apart from the clinical, aspect of the subject.

The section on the Anatomy and Histology of the Intestines is from the pen of J Holmes Smith, M.D , associate professor of anatomy The illustrations accompanying this part of the book are excellent and include those of many dissections which greatly help to explain the letterpress The physiology of the intestines is well described and the chapter on the Utilisation of Food in the Stomach or Intestines of the Healthy Man and under Abnormal Conditions is well worthy of perusal

Dr Hemmeter's views on gastric digestion will require further corroboration before they are generally accepted He believes that the digestive and absorptive capacity of the stomach has been much overrated. He claims that the stomach is nothing more than a reservoir to receive the food and practically to transmit it to the intestine, and that the digestive and absorptive processes which occur in the stomach itself are so insignificant that they may be practically disregarded However, he does not give full details of his reasons for arriving at the above conclusion, since the present volume is concerned with the intestines and not with the stomach

The chapter on Intestinal Bacteria is written by W R. Stokes, M.D , associate professor of pathology and bacteriology in the University of Maryland The author has performed his task admirably and has produced an interesting account of the principal micro organisms which are known to be present under varying conditions in the intestine. Dr Stokes evidently has a thorough knowledge of his subject and is able to express his views in very explicit terms His account of the bacillus coli communis is very clear and accurate and contains a full summary of all that is at present known with regard to this organism.

Chapter IX. is written by Dr H. Adler and is entitled, "Diagnostic Significance of Examination of Fæces and Urine." The macroscopic, microscopic, and chemical examinations of the stools are carefully described. Attention is drawn to the importance of examining the fæces in cases of faulty digestion, so that according to the nature of food matters undigested there may follow a proper selection and preparation of the diet. This point is only too frequently neglected and the digestive organs are loaded with materials of which they cannot make proper use, thus increasing rather than diminishing the digestive troubles from which the patient may be suffering

Turning to the portion of the volume dealing with diet we find much that is interesting After a discussion on the principles of dietetic treatment Dr Hemmeter proceeds to give general rules as to the diet which should be employed in certain forms of intestinal affections, such as dyspepsia (intestinal indigestion) and habitual constipation. The diet tables which are given will be found most useful for reference. They are full and accurate and may be followed with confidence.

The portion of the work dealing with the actual diseases of the intestine is headed, Intestinal Clinic. " Some of the terms will seem strange and perhaps objectional to English readers—such as " obstipation" as a synonym of constipation. The word coprostasis," too is not often seen in English text-books. Setting aside these trivial exceptions we have formed a very high opinion of the value of the work from a practical point of view Diarrhœa, constipation colic, meteorism, intestinal indigestion, and enteritis are all affections met with every day in the course of practice which give *great discomfort to the patient, rendering life most miserable*, yet they are conditions to which speaking generally sufficient attention is not directed by the teachers at the medical schools, and in most text-books they are dismissed very briefly Dr Hemmeter's remarks on the above conditions should therefore prove of considerable value to practitioners His classification, founded mainly on etiology is useful in arriving at a diagnosis and subsequently in coming to a conclusion as to the form of treatment most likely to prove successful in any individual case.

The chapter on Dysentery contains a full account of that disease brought fully up to date. The author insists on drinking water being the most prolific cause of the disease. He discusses at length the various investigations which have been made as to the causal relationship of the amœba coli to dysentery and is apparently in agreement with Kartulis as to its pathogenic value—namely that the amœba coli is the cause of dysentery with the exception of the dysenteries occurring in Cochin China. The illustrations of dysenteric ulceration are excellent. With regard to the treatment of dysentery Dr Hemmeter speaks highly of lavage of the colon, but limits the use of drugs for irrigating purposes to *four substances—quinine*, tannin, *suspensions of bismuth*, and solutions of ichthyol. He advises that the strength of the quinine solution should be one part of quinine to 2500 of water and the strength of the tannin solution 0 5 per cent. The remarks on the use of ipecacuanha are rather surprising He states that his own experience of this drug in the treatment of dysentery as observed in the practice of southern colleagues and in 10 cases of acute epidemic dysentery at Bay View Hospital has led him to discard the drug entirely Kartulis, on the other hand, is of opinion that ipecacuanha has an almost specific influence upon the dysenteric process, but he admits that in severe cases and in amœbic dysentery it is ineffective. These views are conflicting but Dr Hemmeter is supported in his contention by Dr Osler who states that he has never seen the marked beneficial effect of treatment as described by Anglo-Indian surgeons.

The chapters on Ulcers of the Intestine and Intestinal Neoplasms are also very interesting and the illustrations are beautifully executed. We can congratulate Dr Hemmeter on having produced one of the best monographs of Diseases of the Intestines yet published.

Clinical Lectures on Surgical Subjects delivered in University College Hospital By CHRISTOPHER HEATH Past President of the Royal College of Surgeons of England, Emeritus Professor of Clinical Surgery in University College, London, and Consulting Surgeon to University College Hospital. Second Series. London J & A. Churchill. 1902. Pp 345. Price 6s

CLINICAL lectures have a definite function of their own. They are not intended to replace the systematic teaching which the student should obtain in the ordinary course of lectures on surgery, they are intended rather to supplement those systematic lectures—to fill up the lacunæ which are unavoidably left. When delivered by a great clinical teacher they are of inestimable value in the training of the surgeon yet those who have the opportunity of actually hearing them are but few in number and it is the next best thing to be able to read them. Every senior student of surgery and many of those engaged in practice will derive great benefit from perusing these very readable clinical lectures. They deal with many subjects, some so common as " ulcers of the leg " and fracture of the base of the skull", others are concerned with more recondite matters, such as the use of the distal ligature in the treatment of aneurysm," but every lecture is clear interesting and exact. The volume includes two of the Lane lectures delivered by Mr Heath in the *Cooper Medical College of San Francisco in 1897* and also the Hunterian Oration for 1897 Perhaps the most interesting chapter of the book is one to which we have already referred—namely the use of the distal ligature in the treatment of aneurysm, for this is a subject with which Mr Heath's name is closely associated, as he had much to do with the introduction of this method of treatment. It was originally introduced by James Wardrop in 1825 for innominate aneurysm, but Mr Heath's case in 1865 did much to advance the claims of the operation, although it was subsequently found that the aneurysm was aortic and not innominate. The benefit which resulted in that case naturally suggested the employment of ligature of the carotid and subclavian for aneurysm of the aorta itself and though the cases hitherto recorded are not very favourable the method certainly deserves consideration. The chapter gives a very good account of the history and the present position of this operation. We have nothing but praise for the whole book and to only one small slip in the volume would we draw attention. In the account of the points of difference between tetanus and strychnine poisoning it is stated that in the well known Rugeley poisoning case it was proved that whenever the unfortunate victim took any food which Palmer had prepared for him in half an hour he invariably got a fresh access of spasm." This is incorrect. The food that Palmer prepared always contained antimony and caused vomiting the strychnine was only given in pills

---

Clinical Essays and Lectures By HOWARD MARSH F R.C.S Eng Surgeon to and late Lecturer on Surgery at, St Bartholomew's Hospital Consulting Surgeon to the Hospital for Sick Children President of the Clinical Society of London, and Honorary Member of the Medical Society State of New York. London J & A. Churchill. 1902. Pp. 303. Price 7s 6d

IN this volume Mr Howard Marsh has collected some papers and clinical lectures that have appeared in various periodical publications, and he has done well in issuing them in this form for they are of great interest and deserve reprinting There are 20 papers in all and it is difficult to say which is the most important. Perhaps, on the whole, the chapter on Senile Tuberculosis is the most valuable because it deals with a condition the very existence of which is ignored by many medical men. Yet, as Mr Marsh says the disease in its various manifestations is frequent rather than rare its early recognition is often difficult; indeed, it is apt to be overlooked by those who regard it as a mere pathological curiosity " The condition was first described in 1867 by Sir James Paget under the name of senile scrofula" yet at the present time in many text books the subject is not even mentioned Mr Marsh describes a number of cases which give a very clear clinical picture The treatment of senile tuberculosis of a joint is from the first to keep it a absolute rest, but it will unfortunately be seldom of much avail for the prognosis is bad. Another interesting chapter deals with the association of suppuration with malignant disease. The presence of suppuration in connexion with a swelling is very strong evidence against the presence of a malignant growth, but the author relates many cases in which this unusual complication occurred.

The paper on Displacements and Injuries of Muscles and Tendons is also very important Tendons are dislocated much more frequently than is usually imagined, and it is necessary that the surgeon should be well acquainted with this condition, for such cases often drift into the hands of bone-setters who by manipulation reduce the displacement. The same chapter deals with rupture of muscles and tendons from muscular contraction, and many interesting cases are related. Another section is devoted to "rare forms of bony ankylosis," and Mr Marsh shows that ankylosis occurs under many conditions in which it was formerly thought impossible, especially he relates cases which demonstrate that antecedent suppuration is not necessary for the occurrence of ankylosis In conclusion he points out that passive movements cannot prevent bony ankylosis, rather by maintaining irritation and promoting inflammatory exudation they are likely to hasten its appearance We have not space to mention in detail all the papers contained in this volume, but we cannot refrain from expressing our approval of the chapter headed the Etiology of Mistakes in Diagnosis Every surgeon makes mistakes, some of them preventable, others inevitable, but mistakes would be rarer if attention were paid to the points mentioned in this chapter The whole volume is full of interest and will well repay perusal.

A Treatise on the Acute Infectious Exanthemata By WILLIAM THOMAS CORLETT, M D, M R C P Lond. Illustrated. London Henry Kimpton. 1902. 392 pages Price 18*s*

THIS treatise on the acute infectious exanthemata presents the subject with which it deals in a thoroughly practical and efficient manner The difficulty usually experienced in writing satisfactory accounts of dermatological lesions, and more especially those which are peculiar to the infectious fevers, has been in the present instance surmounted by providing a number of coloured illustrations of the common and typical efflorescences. For the purpose of securing the best possible examples of the *dessinateur's* art in the production and reproduction of coloured illustrations the good offices of M Félix Meheux, who has rendered himself famous by his illustration of Chatelaine's admirable work on Diseases of the Skin, have been pressed into the service of the present work The illustrations themselves, with but few exceptions, have been reproduced from photographic negatives taken by the author 12 of them have been reproduced in colour, while 28 are half tone plates and two are engravings The study of these plates will necessarily lighten the task of differential diagnosis which to his confusion often confronts the young practitioner and may to a certain extent fill up a frequent hiatus in his medical equipment. Indeed, as the author admits in the preface, the present volume is the outcome of a similar need for such a work felt by himself "when young in the practice of medicine." The illustrations which constitute so important a feature of Dr Corlett's treatise present with realistic accuracy the delicate and minute shades of colour which characterise the various phases of the different eruptions. And among those which appeal to us as most satisfactory must be included one of varicella in a child which bears superficial resemblance to the rash of small-pox, while another which illustrates the eruption of measles in its typical distribution is equally satisfactory, and another in a distribution which resembles scarlet fever is highly instructive. Finally, we would mention a very beautifully finished illustration of the typical rash of German measles and enlargement of the posterior cervical lymphatic glands The coloured plates representing the small-pox eruption in the various stages of efflorescence strike us as less happy examples of artistic skill and accurate delineation. The individual pustules, as is, indeed, often the case with other photographic representations of skin lesions which are raised above the general plane, give a false impression of magnitude We have, perhaps, dwelt somewhat unduly on the subject of the illustrations, but it is far from our intention to imply that the subject of the text plays a less important part in the general scheme of the work—in fact, had the written portion of the book to rely on its own merits it would assuredly earn considerable success and would merit the attention of all those who are interested in the question of the acute specific fevers The subject of the exanthemata has been approached from the dermatological, rather than from the clinical, side. Nevertheless, the minute description of the pathological appearance has by no means monopolised the author's attention. Questions concerning the etiology, the prognosis, the diagnosis, and the treatment all receive due consideration. Indeed, in view of the fact that to each of the five specific exanthemata included in the scheme there is a practically uniform allocation of 80 pages it may readily be understood that each fever is very fully described Practitioners will find particularly useful the minute and accurate dermatological description of the different rashes with the differential points by which they may be distinguished, not only from one another, but also from other erythematous conditions of independent origin, such as are met with in the efflorescences due to drugs, insect bites, and syphilis Useful also for the same class of readers are the formulary for disinfection especially applicable to the exanthemata and the tables in the addendum which supply the chief features in the differential diagnosis of the various rashes described in the body of the text The treatment of the specific exanthemata, except as regards prophylaxis and the precautionary measures which are necessitated by their infectious nature, is considered in as few words as possible. In the treatment of scarlet fever we notice that he does not take up the illogical and paradoxical position often noticeable in works on this subject of enjoining a strict milk diet for the purpose of limiting the consumption of albumin. A milk diet has, indeed, its advantages, but not specifically for this reason In speaking of the advantages of excluding from the sick room all but the red rays of light in the treatment of small pox the author says that it is impossible to draw any definite conclusions from the few cases in which he has had personal experience of the method, but from the success already obtained by the chemical or active rays of the colour spectrum in the treatment of lupus vulgaris he is led to believe that much good may be accomplished by this method in the management of variola and from the favourable reports already given it is assuredly worthy of further trial. Not only as a book of reference, but as one which affords pleasant and interesting reading, we commend Dr Corlett's treatise to all those who are interested in the subject of the acute specific exanthemata.

LIBRARY TABLE

Phonographic Outlines of Medical Terms Third edition. Issued by the Society of Medical Phonographers, and published by Sir I Pitman and Sons, Limited, London, and G Pulman and Sons, Limited, London. 1902 Price 2*s* —The second edition of this useful book was published in 1898 The present edition contains, as did the previous one, outlines and contractions for about 3000 of the more common medical terms, and a list of similar words 100 new words have been added—e g , "adrenals," "arteriosus," "bilharzia," "biniodide," "hallux," "haversian," schizomycetes symbiotic, but others to be found in the Dictionary have been omitted. The chief alterations are the use of a half length *n* instead of the double length *n* to represent inter "intro," ' enter and the use of the upward *l* instead of the downward in the ' *lymph series. These innovations, no doubt, are* more orthodox though less facile, than those used in the second edition. A few phrases, such as every six hours " have been added , also a few general terms such as "medical officer of health summer session," and up to the time of admission." We think others might be added with advantage. ' Iodide, ' patella," antistreptococcic," antiseptic " "aorta ' calcify desquamation," 'medullary " ' sartorius ' and some others have been altered and no doubt, improved. In analgesia the hard *g* is now represented by *j* By the way phthisis is commenced with a *t* in Pitman s Dictionary owing we suppose, to the erroneous although common pronunciation of phthisis as tisis. We do *not notice 'abortifacient* in the list. Many of the outlines are most ingenious and the book should be welcomed by all medical phonographers —We have also received the *Phonographic Record* for September which contains a further instalment of Disinfection of the Hands," by Mr C. W Cathcart, F R.C.S Eng & Edin.

The Story of Animal Life. By B LINDSAY London George Newnes Limited. 1902. Pp. 208. Price 1*s* —This little book forms one volume of Newnes s Library of Useful Stories. It gives in a plain and simple manner the story of the ascent of animals from the protozoa to man. The last chapter gives an interesting account of ' How Zoologists do their Work."

A Pack of Poems By J L. LONGSTAFFE. London George Allen. 1902. Pp. 86. Price 1*s* net.—All hunting men will welcome Mr Longstaffe s poems. They are real poems with an indefinable kind of eighteenth-century flavour about them. Nor do they deal with fox hunting alone, but with other sports such as golf, and with charity—i.e. with the building of an orphanage. Even the non hunting reader is catered for by such poems as A Duet on Sonnets (from which we should say that Mr Longstaffe, as becomes one who loves the country knows his Theocritus) and A Song of Misery "

A Lady Nurse of the Times By FREDERICK JAMES GANT F R.C S. Eng London Elliot Stock. 1902. Pp. 50. Price 1*s*. net.—Mr Gant must be a veritable Sherlock Holmes in the nursing world. He i. always coming across nurses with a past, which past he dissects with merciless minuteness and puts together again in the form of a story We are glad to say however that Mr Gant informs us in his preface that the heroine of his latest story is dead so that she will not see her life s tragedy in cold print.

European Fungus Flora Agaricaceæ By GEORGE MASSEE, F L.S. London Duckworth and Co. 1902. Pp 274. Price 6*s* net.—This book is a very full catalogue of the agaricaceæ, written in purely technical language. All the agarics of Europe are included and the work will be found very useful to mycologists Altogether 2750 European species are described of which 1553 are British.

Aids to Practical Dispensing By C J S. THOMPSON London Baillière, Tindall and Cox. 1902 Pp. 92. Price 2*s* 6*d* —Practical dispensing as Mr Thompson confesses in his preface, cannot be learnt from a book. But a great many useful hints may be so given and Mr Thompson supplies not a few The chapter on Pill making is very good, but so far as regards medical men who supply their own medicines we fancy that few even if a dispenser is kept, now make their own pills. Mr Thompson s notes about incompatibles" and the dispensing of mixtures containing iron, quinine, and the well known pitfalls of a combination of potassium iodide and spirit of nitrous ether are accurate and striking In the next edition of his book we should advise him to correct the all too commonly found error in grammar—namely the writing "Aquae ad uncias octo or whatever the quantity may be.

Analytical Records

FROM

THE LANCET LABORATORY

MILK OF MAGNESIA

(THE CHARLES H PHILLIPS CHEMICAL CO., 14 HENRIETTA-STREET
COVENT GARDEN LONDON W C. AND 123 PEARL-STREET
NEW YORK, U S.A.)

ON analysis this preparation proves to be quite simple in composition. It consists of pure hydrated oxide of magnesium suspended in distilled water without the aid of the vehicles commonly employed in emulsions and without aromatics. It is quite uniform and the hydrate shows no tendency to separate. The preparation neutralises acids as speedily as does a clear solution of the alkalies, so that it serves as an efficient antacid with the advantage that no gas is produced as when a carbonate is used On mere evaporation the hydrate is obtained in a pure state and on ignition the oxide. The residue contains just a trace of carbonate. The amount of hydrate which we found was 6 13 per cent. which is equivalent to the amount stated to be present—namely 24 grains in each fluid ounce. The preparation serves as a mouth wash and possesses obvious advantages as an antacid. Of course, the salt of magnesia formed as the result of neutralising an acid has generally a slight laxative effect.

(1) CHOCOLATE WITH DEVONSHIRE CREAM; AND (2) VANILLA LUNCH CHOCOLATE.

(JOHN CLEAVE AND SON CREDITON DEVON)

1. In this preparation a comparatively large proportion of Devonshire cream has been combined with the chocolate with success and a very palatable and nutritious sweetmeat is the result. 2 The lunch chocolate is an excellent example of the employment of ingredients of high quality We have evidence before us showing that the choicest materials are used in the preparation of these sweetmeats and that they are prepared with a strict regard to cleanliness We have remarked before on the very great advances that have been made in the manufacture of confectionery care now being taken not only to select good and wholesome materials, but to manufacture them also under healthy environments.

THE WINJENNIA REMEDIES

(THE WINJENNIA PROPRIETARY LIMITED MELBOURNE AND SYDNEY;
W H. SMITH 47 ALDERMANBURY LONDON E.C)

We have received specimens of an ointment and a lotion which contain a powder described as a volcanic deposit to which certain curative effects are ascribed. The powder on analysis proved to contain chiefly the sulphates of iron and alumina, which are soluble in water while the insoluble portion contained silica associated with alumina and ferric oxide The ointment and lotion contained the soluble salts described. The lotion is said to be useful in the treatment of sores in cattle. The sulphates of iron and alumina possess, of course some germicidal power while they are astringent. It is conceivable, therefore, that their application in some cases would do good The "remedies," however, are clearly old-fashioned and crude.

OOWANA SOAP

(OOWANA, LIMITED, 205 VICTORIA STREET LONDON S W)

Our examination of this soap gave satisfactory results It is free from alkaline excess and irritants and is bland and soothing to the skin The soap is said to be made from edible fats and a fluid vegetable extract is added to it, an addition which is said to enhance the cleansing properties of the soap while contributing to its favourable action on the skin The soap is dark olive brown in colour and is agreeably scented

SCOTCH WHISKY (THE QUEEN'S BRAND)

(BEARDMORE AND CO, LONDON AND GLASGOW LONDON AGENTS, F H. AND F J GREEN, 2 GRESHAM BUILDINGS, LONDON, E C)

This spirit is described as a "small still Scotch malt whisky" The evidences of analysis and taste are in favour of the statement that it is both old and pure. The results of analysis were as follows alcohol, by weight 42 29 per cent, by volume 49 81 per cent, equal to proof spirit 87 29 per cent.; extractives, 0 29 per cent, mineral matter, 0 01 per cent., and total acidity reckoned as acetic acid, 0 024 per cent The flavour is mild and characteristic of genuine malt whisky Much of the whisky of the present day is featureless as regards flavour This whisky is practically free from acidity and sugary constituents It is without the bad physiological effects of crude spirit

DIGESTIVE PEA FLOUR

(THE DIGESTIVE FOOD CO MURRAY-STREET PAISLEY)

By a special mode of preparation this specimen of pea-flour has been reduced to an easily digestible state This is evident from the fact that it contains a larger proportion of soluble constituents than does raw pea flour We have obtained the following results on analysis moisture, 7 89 per cent, fat, 1 24 per cent, mineral matter, 2 61 per cent, proteids, 19 05 per cent., and carbohydrates, 69 21 per cent. The preparation contains 100 per cent. less moisture than dried peas do, a result probably obtained by cooking This reduction is important as it raises the proportion of carbohydrates as well as of proteids

SPECIAL DISINFECTANT SOAP

(HAROLD HFYDON AND CO, 118 WESTON STREET BERMONDSEY LONDON, S E)

As is not always the case with disinfectant soaps, the disinfectant agent used in this instance is of an agreeable character The smell of the soap suggests oxidised pine oil or oil of turpentine The soap basis is well prepared since it contains no alkaline excess and is free from foreign ingredients commonly added to soap The soap produces a free and pleasant lather without waste and has an agreeable effect upon the skin, imparting to it a delicate pine like smell Soap itself possesses some antiseptic value and in this instance this value is undoubtedly accentuated

(1) MOUTH WASHES AND (2) TOOTH POWDERS

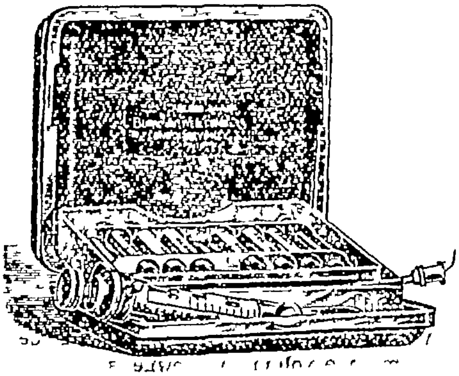
(MESSRS ROUSE AND CO 12, WIGMORE STREET, LONDON W)

The composition of the mouth washes and tooth powders, two of each of which have been submitted to us, is based on formulæ of well recognised value. They contain antiseptics and disinfectants adapted particularly for preserving an aseptic condition of the mouth The formulæ are said to be the outcome of suggestions made by dental authorities The washes and powders contain no injurious constituent and are pleasant as well as effective

New Inventions.

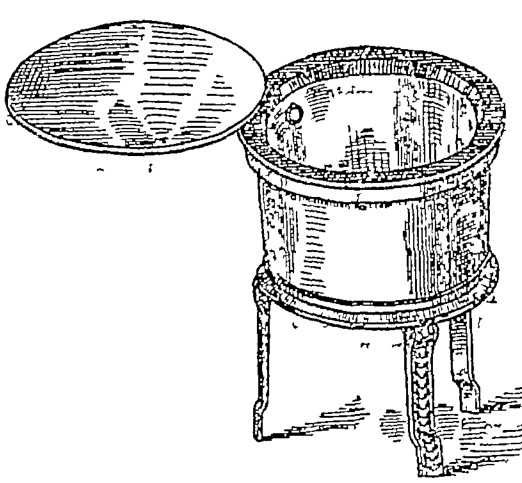
A NEWLY ARRANGED HYPODERMIC SYRINGE AND CASE

A NEWLY arranged case for hypodermic medication has been submitted to us by Messrs Burroughs and Wellcome The syringe itself is entirely made of glass and is (unlike many syringes with glass pistons) accurate and free from leakage. But we should always advise purchasers of such instruments to select their own, as the calibration of such small syringes and pistons is very difficult and often faulty, hence the pistons leak. This case is fitted with a moveable rack containing 12 tubes of tabloids, two needles, and an exploring needle The arrangement of the tubes is very ingenious and with a little practice quite simple, the rack swings on its short axis and is so arranged that no tube can fall out. The whole rack, needles, and syringe can be readily boiled after removing the tubes The outer case is very strongly and carefully made of "gun metal" with nickel plated rims



A PORTABLE COMMODE

Messrs Henry Cowley and Co, Limited, have submitted to us one of their portable commodes It is made of porcelain, provided with a wooden rim and a metal lid which are detachable, and is inclosed in a metal cover It fits on to a metal tripod stand. For purposes of carriage the stand can be inverted and the commode fits inside the legs The whole is then inclosed in a tin box of about the size of an ordinary bonnet box. In this country nowadays the sanitary arrangements of hotels and lodging houses are usually fairly satisfactory, but this is far from being the case in many places on the continent, and we should say that Messrs Cowley's invention would be of great use to ladies travelling abroad.



THE LANCET.

LONDON SATURDAY SEPTEMBER 13 1902.

The Election of a Direct Representative on the General Medical Council

FRIDAY September 5th, was the last day for the receipt of the nomination papers of candidates for the seat on the General Medical Council as a Direct Representative for England and Wales that is now vacant by the expiration of Sir VICTOR HORSLEY'S term of office. We understand that Mr JOSEPH SMITH of Chiswick, an ex president of the Association of Incorporated Medical Practitioners, will seek the suffrages of his fellow practitioners, but we cannot say that we think his proposed action an advisable or convenient one. Sir VICTOR HORSLEY has done good and fearless work upon the Council, and thoroughly deserves a further term of office. He has been one of the engineers of the new constitution of the British Medical Association and it is really important that he should be able to explain to the General Medical Council the views and working of the Association should occasion arise. He enjoys the confidence of a very large section of his constituency and his ability and energy are too conspicuous to be called in question even by those who do not see eye to eye with him upon all matters We are certain that if the principle of direct representation is to mean anything and if the voices of the Direct Representatives are to carry weight in the deliberations of the General Medical Council, contested elections should be avoided as much as possible. It seems impossible, while human nature is what it is, that any election for any post can be carried on between rival candidates without a certain amount of asperity being introduced into the relations between them If Mr SMITH persists in his ill advised intention to go to the poll whichever candidate proves to be the successful one will have a weak position. It is almost inconceivable that Mr SMITH should succeed against a man of Sir VICTOR HORSLEY'S tried ability and record of arduous service, and in the circumstances the profession will be right to resent having the inconvenience of an election thrust upon them.

It has been suggested by Mr GEORGE BROWN—at least we read his not very comprehensible letter in the *British Medical Journal* of August 30th as conveying this suggestion—that *the territorial principle of representation* demands the replacing of Sir VICTOR HORSLEY by some one not resident in London We would suggest to Mr BROWN that if he feels at all acutely the fact that London has no right to two Direct Representatives—and we are somewhat in sympathy with the view—he himself should resign and should allow a provincial medical man to succeed to a seat upon the Council without an election. An election is not wanted just now What is wanted is the rousing of the General Medical Council to a sense of the present position of the profession. We can conceive no clearer voice than Sir VICTOR HORSLEY'S for demonstrating the problems of medical politics to the Council and whoever obstructs his re-election stands in the way of medical progress. As is perfectly well known to all our readers we are frequently in disagreement with Sir VICTOR HORSLEY—a position which that gentleman's temperament probably compels him to view as foolish on our part, but while we make occasional reservations in our approval of his procedure as a medical politician we have no doubt whatever of the excellence of the work that he has done upon the General Medical Council. We trust that all our readers should this election be forced upon the profession, will register their votes for Sir VICTOR HORSLEY

Obliterative Arteritis

THE constriction and closure of large arteries have been described by various observers, but the condition is rare Professor FRIEDLÄNDER in 1876 described a disease to which he applied the term "obliterative arteritis." The causes of the complaint are unknown but it is often accompanied by neuritis, and, like all anatomical modifications of the lumen of the arteries of the limbs which end gradually in occlusion, it may engender various premonitory symptoms long before it culminates in gangrene. According to Dr F W MOTT (writing in Professor CLIFFORD ALLBUTT'S "System of Medicine" vol. vi. p. 301) the main symptoms are pain in the limbs, intermittent cyanosis cramps, coldness and numbness—conditions which transitory at first, afterwards instal themselves permanently Sooner or later the pulse is no longer felt in the course of the arteries and the temperature of the part is lowered. Ecchymotic patches appear at one or several points chiefly at the extremity of the limb. Eschars arise and the gangrene, sometimes moist, sometimes dry spreads with more or less rapidity The lower limbs are affected more often than the upper but the symptoms may begin in the hands the affection is frequently but by no means necessarily symmetrical. Authorities are not altogether agreed upon even the pathological nature of obliterative arteritis and Dr MOTT states that it is not associated with any particular diathesis or with any acquired disease But the morbid anatomy of the condition, according to the same authority consists in thickening of the walls of the arteries due to cellular proliferation of the endarterium and hypertrophy of the middle and external coats there is also seen a development of vasa vasorum in the middle and external coats and inflammatory thickening of the small vessels leading to complete occlusion. The obliteration of the lumen of the artery may be due to thrombosis or to proliferating endarteritis.

In another column we publish details of a case presenting exceptional features of interest and reported by Dr J A. ARKWRIGHT The heading as given by the author is— "A Case of Hæmophilia in a Woman with Symptoms of Defective Circulation in the Legs and Threatened Gangrene of the Toe, Death with Cerebral Symptoms." The chief points of the case are as follows The patient was a woman, aged about 30 years at the time of her death, who at various periods of her life had manifested the symptoms of hæmophilia, especially on tooth extraction. Seven years before her death she had complained of aching pains in the lower limbs, which persisted for some weeks About a year before she died marked circulatory changes were noticed in the legs, the left limb being colder than the right and a variable purple mottling was present on the skin of the left below the knee In the winter the ends of the toes of the left foot became black and purple and gangrene threatened. This condition passed off with rest and elevation but later returned. Subsequently circulatory disturbances were observed in the upper limbs. Both legs then became mottled and pulsation could not be felt in certain of the arteries Spontaneous hæmorrhage occurred from the gums Arthritic symptoms resembling those so often associated with hæmophilia also occurred She died rather suddenly with symptoms of cerebral hæmorrhage As will be perceived, the symptoms occurring in this case present some similarity to those characteristic of obliterative arteritis Hæmophilia, as is well known, is far more common in males than in females, indeed, some authorities doubt its existence in women. In the case under consideration, however, the patient certainly seemed to be the subject of a hæmorrhagic diathesis, which is simply a synonym for hæmophilia. The tendency to bleed was shared by a brother in a slight degree, but this tendency could not be traced to a former generation The swelling and effusion of blood into the joint after a comparatively slight injury were also suggestive of hæmophilia The pain in the limbs, however, is not characteristic of this disease. Dr ARKWRIGHT remarks that the coldness and deficient blood supply to the lower limbs had some resemblance to Raynaud's disease, but rightly adds that the symptoms were too persistent and progressive and did not intermit with sufficient completeness to agree with the classical description of that disease, moreover, the symmetry was very imperfect. Further, exacerbations were generally excited by the use or dependent position of the legs and were not truly paroxysmal The symptoms observed in obliterative arteritis, especially in the early stages, also resemble those of Raynaud's disease, thus, before the obliteration of the vessels is complete there may be intermittent claudication in the limbs associated with cyanosis and coldness of the extremities

We are not aware whether the arteries in the brain have been found likewise degenerated in other cases which have been recorded, for if the cerebral arteries do partake in the degenerative process the mode of death would be accounted for—cerebral hæmorrhage due to diseased arteries The fact that Dr ARKWRIGHT'S patient was the subject of the hæmorrhagic diathesis would also raise the point as to whether a condition of hypoplasia of the vessels might have existed. The etiology of obliterative arteritis has not yet been fully worked out, but syphilis in some of the recorded cases appears to have been the principal factor Arterio-sclerosis, with or without syphilis, and strain, have also been ascribed as capable of producing obliteration of the vessels and in some extreme cases of this nature the arteries have been found converted into fibrous cords As we have already stated, well marked instances of obliterative arteritis are rare and, in fact, some writers deny that this special form of arteritis exists and maintain that Professor FRIEDLÄNDER and others have mistaken for it a thrombus replaced by connective tissue occurring in an artery affected with arterio sclerosis With pathological conditions of only occasional occurrence it is necessary to wait for further cases to be recorded before a definite conclusion can be arrived at Doubtless some cases of Raynaud's disease have been really instances of obliterative arteritis We have drawn attention to this condition after reading the case described by Dr ARKWRIGHT, which presents symptoms suggestive of the possibility of the presence of obliterative arteritis

The London County Council and Inquests

THE annual report of the Chief Officer of the Public Control Department of the London County Council for 1901–1902 contains, among other matters, interesting statistics relating to the inquests held by coroners within the Council's sphere of activity and various deductions and recommendations based upon these which may be taken to be before the Council as embodying the views of its Public Control Committee The London County Council appoints the metropolitan coroners except in certain districts and in some localities where it does not appoint, as well as where it does, it pays their salaries, settles their districts, maintains their courts, and defrays the costs of their inquiries In the year under consideration notice of uncertified deaths was given to coroners in London, excluding the city, in 9832 cases, and in 7932 of these inquests were held, the cost for the year, including the salaries of coroners, being returned at a little over £32,000 This is a large sum of money, and it is clearly the duty of the London County Council to scrutinise its disbursements and to make sure that all money spent goes to the accomplishment of some useful object, but at the same time £32,000 is not a very large portion of the Council's total annual expenditure The holding of inquests in proper cases is a matter which closely affects the public health and safety and inconsiderable economy, if it results in the smallest diminution of efficiency, is to be deprecated.

We gather from the report before us that the public control department of the London County Council regards with disapproval an undoubted increase in the number of inquests held in London and in their cost which is to be observed during the past few years and that it suggests as a means to diminish their numbers the institution of preliminary inquiries of a nature not at present provided for by the law These inquiries, it suggests, should be made by specially appointed "medical investigators" who should inquire as to the causes of uncertified deaths, examine the body in all cases, and hold post-mortem examinations where necessary, reporting the result to the coroner, and afterwards giving evidence and acting as medical advisers to the coroners should the latter officials desire to hold formal inquests

When, if ever, these proposals are embodied in a Parliamentary Bill it will be time to deal with them in detail and, for example to point out that an official who not only appears as a witness but at the same time advises the presiding judge (himself frequently a medical man) upon medical matters is likely to be looked upon as an institution rather novel than desirable. Upon general grounds, however we would suggest to the County Council should it be considering the proposals of its public control offices, that the increased number of inquests *is not necessarily* a cause for dissatisfaction but is probably the result of the increased vigilance of its officers and of a growing feeling in favour of the prevention of avoidable mortality

The view submitted to the County Council upon this head appears from the following passage in the report It appears probable that a proportion of the inquests held was unnecessary as in no less than 3935 cases—almost precisely one half of the inquests held—the verdict of the jury was Death from natural causes. " We, on the other hand, hold the opinion that no such inference can be drawn from the figures and fact stated, believing as we do that if thousands of deaths take place in London as to which no medical man will certify it is for the public safety that all should recognise it as almost inevitable that deaths so uncertified will be followed by inquiry It is true that the creation of a medical investigator is suggested to the County Council as a means by which inquiries may be held without formal inquests but the essential merit of the inquest which at present has its admitted defects, lies in its publicity and its formality A medical investigator could only be a practitioner instructed to ascertain as far as possible the actual cause of death, to which his inquiry would be limited. Even in this he might be regarded as a person holding an inquisitorial position and one from whom information should be withheld it would not be right that he should play the part of a detective suggested by the novel and undesirable title of medical investigator " His inquiry moreover would be one of a more or less private nature and might be held without the advantage of the evidence of persons able to impart valuable information The inquest, on the other hand *is* publicly held and publicly reported so that public opinion is brought to bear upon the matters disclosed and so that those who have anything to say as to relevant facts may at any time learn that it is taking place and come forward to give evidence or may give information afterwards if *relevant facts have been suppressed. No inquiry* therefore by an ' investigator " medical or otherwise, can in any way take the place of a coroner's inquest and it does not seem to us that the medical investigator could properly do more than can now be done by a medical practitioner employed in the usual way by the coroner to hold a post mortem examination.

It is however submitted to the County Council in the report before us that the general practitioners who now usually make the post mortem examinations are rarely qualified by experience for the work and it may be that a proportion of the post mortems now made are of little value in determining the cause of death." The writer of the report having made this statement without adducing evidence in support of it goes on to suggest that a well qualified pathologist experienced in making post-mortem examinations should be employed in each district," and being fond as will have been seen, of airing speculative theories he adds There are probably many capable young pathologists attached to London hospitals who would be glad to undertake work of this nature at an all round fee of say one guinea per case on the understanding that a considerable number of cases would be referred to them

Among the further theories put forth in the text of the report as distinct from its statistics we observe the suggestion openly made that coroners multiply inquests because their salaries are based upon a scale proportionate to the number of inquests held and this is coupled with the recommendation that they should be paid regular salaries independent of the work done as a means to diminish the number of inquiries and the consequent expense to the Council That coroners should have fixed incomes may be very desirable, but we emphatically protest against the allegation that this should be done on the ground that they now increase their emoluments by corrupt methods With regard to the report as a whole, it contains interesting figures and statistics and perhaps the germs of useful alterations in the regulations governing the holding of coroners inquiries. It will, however we hope be long before the County Council is permitted to introduce innovations tending to diminish the number or the thoroughness of inquests, which whatever their defects may be, undoubtedly play a considerable part *in the safeguarding of life in the metropolis and indeed* throughout the country

Annotations.

Ne quid nimis."

DEATH OF SIR FREDERICK ABEL.

THE death of Sir Frederick Abel G C V O K C B removes undoubtedly our greatest authority on the chemistry of explosives. At the outset of his career he was quickly associated with research work into the physics and chemistry of gunpowder and other explosive agents. Indeed the transition from what may be called the gunpowder period in regard to explosives for military purposes to the nitro explosives period was due to Abel's brilliant researches while Professor of Chemistry at the Royal Military Academy and chemist to the War Department. Sir Frederick Abel cannot be said to be the founder of nitro-explosives but undoubtedly he was the first to recognise the value of applying nitro-explosives as the projecting force for guns. He studied very minutely the conditions under which the nitro-compounds could be adapted for the purpose Practically the results of his study of this application proved the death knell of gunpowder in favour of smokeless powder Abel's name will perhaps be best remembered by the public by his connexion with the cordite case. He was accused by Nobel of having acted in bad faith by as Nobel asserted having adopted a powder practically of the same composition as the one he had invented (ballastite) for the Government's exclusive use In other words Nobel claimed that cordite was a piracy of ballastite. It is almost fresh in our memory that Abel pointed out a very essential difference between the two which made the former safe and effective for ammunition while the latter was not trustworthy The circumstances of the case were that Abel was appointed by the Government to determine what powders existed which could be substituted with advantage for gunpowder and the reply of Abel and his colleague, Professor Dewar, was that at the time of their investigation there existed none. It cannot be gainsaid, however, that through this investigation Abel conceived in what respects nitro-powders were unsuitable and his subsequent research upon the subject resulted in an improved powder which fulfilled all the conditions required for an explosive for ordnance use Thus the charge of bad faith failed. Sir Frederick Abel's work, however, was not confined to the practical study of explosives He was appointed to inquire into the safe storage of petroleum oil and at the present time regulations exist as to the sale, storage, and use of petroleum oil which owe their origin to the results of Abel's inquiry Amongst other things he invented a flash point apparatus for the testing of oil, an apparatus which is officially recognised at the present time Sir Frederick Abel devoted himself also to the investigation of other branches of science, such as, for example, to the improved manufacture of iron and steel, especially in their relation to the requirements of war material He was, again, an eager student of pure science and communicated a number of papers chiefly to the Chemical Society and the Royal Society embodying scientific research. Sir Frederick Abel during his career occupied the offices of President of the Chemical Society, of the Institute of Chemistry, of the Society of Chemical Industry, and of the British Association The death of Sir Frederick Abel will be a melancholy fact to his colleague, Professor Dewar, as having taken place on the eve of his presidency of the British Association this week at Belfast. Sir Frederick Abel proved a faithful servant to the Government and his place as official adviser to the War Department will be hard to fill.

THE MEDICAL LANGUAGE OF ST LUKE

THE recently announced death of the Rev William Kirk Hobart, rector of Killanny, co Louth, removes from the not too numerous experts in Greek medical literature one of the ablest and most accomplished of the band—the author of the treatise, familiar to theologian and philologist alike, entitled "The Medical Language of St Luke a Proof from Internal Evidence that the Gospel according to St. Luke and the Acts of the Apostles were written by the Same Person and that the Writer was a Medical Man." Appropriately dedicated to that eminently Biblical scholar, the present Primate of Ireland, Dr Hobart's work was published 20 years ago, welcomed by THE LANCET at the time in an extended review, and is now secure in an honoured place in the *apparatus criticus* of the evangelist whose "Gospel" Renan has called the "loveliest book in all literature," and whose "Acts" is pronounced by Professor W M Ramsay to be redolent of "genius, skill, and sympathetic historical insight" No doubt, as we indicated in our critical notice,[1] Dr Hobart is, on occasion the victim of his own enthusiasm, apt to find in St. Luke's phraseology an exclusively medical idiom when there is evidence to show that the word, or words, cited had passed from professional into general currency Dr Plummer, Master of University College, Durham, in his very scholarly and able commentary on the Gospel, supplies cogent proof of this, while cordially admitting the value of Dr Hobart's labours Another defect of the treatise is the preference given to Kühn's uncritical recension of the Greek medical writers (Leipsic, 1821–30) over the far sounder texts of Hippocrates as constituted by Littré (Paris, 1839–61) and by Ermerins (Utrecht, 1859–65), to say nothing of the still more correct edition now in course of publication by Kühlewein in Teubner's "Bibliotheca Scriptorum Græcorum et Romanorum." Aretaeus, moreover, appears to be known to Dr Hobart only in the superseded text of Kühn and not in that of the standard edition executed with masterly skill for the Sydenham Society by Dr Francis Adams of Banchory (London, 1856) These defects, we repeat, detract from the merit of Dr Hobart's treatise, but when every allowance is made for them that treatise remains a monument of labour almost "Benedictine" in its assiduity and of learning and acumen well worthy of its sacrosanct theme Its publication by the press of Dublin University, of which its author was a distinguished graduate, does honour to that seat of learning, but for whose liberality it would probably never have seen the light. Dr Hobart, indeed, conveys as much in his preface, while his comparatively premature death calls for a renewal on our part of the tribute paid 20 years ago to his ample vindication of the third Gospel and of the Acts of the Apostles as incontestably the work of the "Beloved Physician"

PTOMAINE POISONING

A SERIOUS epidemic of food poisoning has occurred in Derby and naturally a good deal of alarm is felt It is roughly estimated that the number of cases has been 150 Fortunately, the type of disease has not been, in Derby at least, very severe and with one or two exceptions all the persons attacked have recovered or are progressing favourably At Taunton, however, the death has occurred with symptoms of ptomaine poisoning of a man, aged 75 years The deceased returned home on the evening of Sept 8th from Derby, bringing with him a pork pie purchased there He, his wife, and a servant all ate of it and the following day all three were taken ill, the man dying at night The source of the poisoning is suspected to lie in certain pork pies purchased from one of the best-known pork butchers in Derby This theory is also supported by the fact that a visitor to Derby brought back with her to her home in London a pork pie from the same shop All the persons who partook of the pie suffered with the characteristic symptoms of ptomaine poisoning Samples of the suspected food have been sent to Dr Delépine for analysis. As in the case of similar epidemics the symptoms have not occurred as the result of eating meat actually "putrefied"—that is, of meat the smell of which would at once give rise to suspicion. It is known from actual experiment that the most toxic products of putrefaction are present in the earlier and not in the later stages of the process.

GASTRECTOMY

RECURRENCE after removal of a malignant growth from the stomach may occur either locally in the gastric wall or in the lymphatic glands Mikulicz has laid much stress on the frequency of local recurrence and points out that a sufficient portion of the stomach is usually not removed. In our present issue appears a paper by Mr G A. Syme of Melbourne on a successful case of gastrectomy for malignant disease, in which he advocates removal of nearly the whole of the stomach for gastric carcinoma, for, he maintains, if operation is advisable at all gastrectomy is indicated, since, as the presence of the stomach is not essential for digestion, the more complete its removal the greater the probability of immunity from recurrence, while the increase in the risk is not proportional to the amount removed. Mr Syme considers it wise for ease in operation to leave a small portion of healthy stomach There is much to be said for this view, for at present an ordinary pylorectomy for a malignant growth is only too frequently followed by a return of the disease in the stomach, showing that too little of that viscus has been removed. In some points a gastrectomy is an easier operation than a pylorectomy, for it is less difficult to anastomose the duodenum to the cardiac end of the stomach than to join it to the middle of the organ where the calibre is much greater. Naturally the more of the stomach removed the greater is the shock, but there is no exact proportion between these variants and the shortening of the operation due to the increased facility of performance will of itself diminish the amount of shock. For statistical purposes it is desirable to distinguish between complete gastrectomies and almost complete gastrectomies; in the former no portion of the stomach wall is left behind, the œsophagus being united to the intestine. In almost complete gastrectomies some part of the cardiac end of the stomach is retained, it may be only a few lines in breadth or it may be one or two inches. *This distinction is necessary* or confusion will arise. Up to the present only about a dozen complete gastrectomies have been performed, but there have been many cases in which more than three-fourths of the stomach have been removed. Mr Syme's suggestion that we should remove the greater part of the stomach in all operable cases of gastric malignant disease is well worthy of and will doubtlessly receive, the careful consideration of surgeons in all parts of the world.

---

[1] THE LANCET, June 9th 1883 p 1002

THE CONTAMINATION OF ICE-CREAM

THE making of ice-cream, carried on so frequently by poor Italians in our large towns no doubt requires supervision. A cheap ice seems to be an irresistible temptation to town children even when there is but little regard for cleanliness in the seller and his surroundings. Two Italians were summoned recently by the sanitary committee of the corporation of Manchester for omitting to take proper precautions for the protection of the ice cream which they made from infection or contamination and were fined respectively 10*s.* 6*d.* and 21*s.* and costs. Two other Italians were at the same time similarly fined for making ice-cream in a yard in which there was an inlet or opening to a drain being an act likely to expose such ice-cream to infection or contamination.' Such cases as these are often occurring and will do so as long as the providers of this luxury make it in all sorts of dirty unfit places, which they will continue to do whilst there is a paying demand for ice-cream. But a movement has been begun by the principal makers to provide a building where it can be made under cleanly and sanitary conditions. It is very desirable that this should be carried out.

THE FORENSIC IMPORTANCE OF DISTINGUISHING BETWEEN THE CONTENTS OF THE SMALL AND LARGE INTESTINE.

THE forensic importance which a minute point in physiology may assume is well illustrated by a case related in the *New York Medical Journal* of July 26th by Professor Austin Flint. A prostitute went to a room in a disreputable hotel about midnight with a man who disappeared in the night and was never discovered. In the morning she was found strangled and mutilated. A man who occupied the opposite room in the hotel and was seen to enter it about 1 A.M. and to leave it about 5 A.M. was charged with the crime. The theory of the prosecution was that he entered the room of the deceased after her companion had left. On his shirt and stockings, on the bed ticking floor and door of his room, on a knife found in his room, and on the floor between his room and the woman's room mammalian blood was found. On matter taken from under the prisoner's long finger nails bilirubin, tyrosin, cholesterin, triple phosphates columnar epithelium, eggs of round worms starch granules, and partially digested muscular tissue and vegetable matters were found. Before Professor Flint was employed in the case the experts thought that these substances came *from* the large intestine. They understood that a piece of intestine cut out by the murderer was from the large intestine. Though assured of this Professor Flint insisted that the substances came from the small intestine. On referring to the record of the necropsy he found that a portion of the lower part of the small intestine had been cut out and that the large intestine was uninjured. He based his opinion mainly on the presence of tyrosin and bilirubin. In the large intestine the tyrosin would be changed into indol and the bilirubin into stercobilin or hydrobilirubin. This reasoning applies only to normal digestion, in some forms of diarrhœa and in Asiatic cholera tyrosin may be found in the fæces similarly in certain pathological conditions bilirubin may be found in the fæces. The forensic importance of the point arose *from* the defence assuming that fæcal matter (i.e. contents of the large intestine) might be found under the finger nails of persons of grossly uncleanly habits. Of course no such explanation could apply to substances found only in the small intestine. The prisoner was convicted of murder of the second degree.

BACCELLI'S TRIBUTE TO VIRCHOW

AMONG the many Immortelles laid on Rudolph Virchow's tomb by his European contemporaries, that of Dr Guido Baccelli, Minister of Agriculture in the Italian Government, may be taken to express the feeling of Italy not only in the medical profession but among nature students throughout the kingdom. We translate it textually as given in the telegram despatched by His Excellency to Professor Posner of the Berlin University. Wherever the whole world over science and *freedom* integrity and character are held dear the highest honour will be paid to the memory of Rudolph Virchow. A light and ornament of our friend Germany he was for more than half a century the master acclaimed by all masters, in the domain of medical culture. For us Italians he was ever the tender friend, unforgetting and unforgotten. I think I see him still at Berlin on the day of his apotheosis as he sat in the august assembly on a chair enwreathed in laurel, concealing from himself with the sweet serenity of a great soul the triumph he had earned, so as to leave his heart free to its loving sense of gratitude. I beg you, my dear Posner to convey to his family to his colleagues to his friends our deep fraternal sorrow—sorrow tempered only by the words of Tacitus *Non est lugenda mors quam immortalitas consequatur*

VENOUS THROMBOSIS IN PNEUMONIA

THOUGH many cases of venous thrombosis in typhoid fever and influenza have been recorded this complication appears to have been seldom observed in pneumonia. In an important paper published in the *Johns Hopkins Hospital Bulletin* for June, Dr Walter R. Steiner states that he could collect only 39 cases of thrombosis in pneumonia. In 27 out of 32 cases the thrombosis occurred during convalescence in one case on the day of the crisis and in four cases during the course of the disease. The lower limbs were always affected. As in typhoid fever and other infections the left femoral vein was usually involved. Dr Steiner relates three cases of thrombosis which occurred in a series of about 600 cases of pneumonia in the Johns Hopkins Hospital. Case 1.—A negro, aged 21 years was admitted on Jan. 9th 1899 the fifth day of an attack of double pneumonia. The crisis occurred on the ninth day. Seven days later when resolution was progressing slowly the temperature suddenly rose and there occurred a chill and prune juice sputum." No further involvement of the lungs could be detected. The temperature remained elevated for five days. Four days after its fall thrombosis of the right popliteal vein and œdema of the foot and leg ensued. The temperature rose to 100·8° and there was pain in the leg, especially in the calf. Under a lead and opium lotion the pain was relieved and the swelling was reduced. Case 2.—A man, aged 63 years, a heavy drinker, was admitted on Feb. 1st, 1901, the eleventh day of an attack of pneumonia of the right upper and middle lobes. A systolic murmur was heard at the apex. Three days later the varicose veins of the right leg began to be painful, especially above the knee, where they were red, firm, and tender. Two days later the right internal saphenous vein was visible and cord like on palpation. He gradually sank and died. At the necropsy thrombosis of the right internal saphenous vein was found. Case 3.—A negro, aged 22 years, a hard drinker, was admitted on Jan. 4th, 1902, the fifth day of an attack of pneumonia of the lower left lobe. Resolution was slow and the temperature reached normal on Jan. 21st. Six days later there was pain in the right leg. In the popliteal space was a tender, cord like swelling of the size of the little finger. It could be traced down to nearly the lower third of the leg. Recovery followed and he was discharged on March 4th with the popliteal vein no longer palpable.

A DEAR PISTOL.

WE have frequently pointed out that a licence is required for the carrying of a revolver as in the case of other "guns," and have suggested that if it were possible to enforce the law in this respect some small check might be placed on the free handling of firearms by boys and others, although, of course, more effective legal facilities are required if the evil is to be satisfactorily dealt with. At the police-court at Stratford a youth was recently summoned by Mr. Hodges, a vigilant Excise officer, who saw him show a revolver to a friend and at once asked him if he had a licence to carry it. The conscience-stricken youth, who of course had no licence, promptly proceeded to the post-office and bought one, taking what was no doubt a prudent course in order, if possible, to propitiate the bench by complying with the law as far as lay in his power, though in a somewhat belated fashion. This took place on July 25th and as such licences run from August 1st in any given year the defendant's licence only lasted for five days and the Excise for once had the best of it. It was stated in court that he had broken up his revolver—no doubt in disgust at the expense in which it had involved him—and he was only fined the nominal sum of 2s. 6d. with costs. It must be remembered, when we congratulate Mr. Hodges on his effective action, that it was merely by accident that he saw the revolver exhibited in public and was able to take out the summons, and that any man within his own home and the "curtilage" thereof may keep a pistol without having to pay for a licence and without anybody troubling about it until he shoots himself or somebody else.

FINAL PROGRAMME OF THE SIXTH INTERNATIONAL CONGRESS OF CLIMATOLOGY.

THE final programme of the Sixth International Congress of Hydrology, Climatology, and Geology has now been issued and it offers a very attractive series of excursions at a comparatively moderate cost. On Monday morning, Sept. 29th, the opening ceremony will take place at the town hall of Grenoble, to be followed by a visit to the monuments of that most picturesque city. In the afternoon the sections will meet at the School of Medicine and there will be a banquet at the town-hall in the evening. In the afternoon of the following day there is to be an excursion to Uriage and on Wednesday afternoon to Allevard. The sections will meet in the morning of those days, but the whole of Thursday is to be devoted to visiting the plateau of Petites Roches, the climatic station in the mountain of the Chartreuse, and the valley of Graisivaudan. Another party will go to Villard-de Lans and the climatic station of Vercors. The discussions are to be resumed on the Friday morning and continued all day. On Saturday also there will be two sittings, and the business of the Congress will then be concluded; but on Sunday, Oct. 5th, there is to be a great excursion to the Grande Chartreuse and a visit to the convent, and the members will sleep at Aix-le-Bains. On Monday, the 6th, they will visit Aix les Bains, the lake of the Bourget, and the Revard climatic station; the members will then part company. The whole of these excursions, including meals, will not cost more than £2, and those members whose names were inscribed before Sept. 10th will obtain a 50 per cent. reduction on the French railway fares to Grenoble. The scientific discussions to be held will be in accordance with the programme published in these columns on July 19th last. The subscription for membership is 20 francs, which should be forwarded to the general secretary, Dr. Fernand Berlioz, à l'Ecole de Médecine, Grenoble, Isère, France.

CHOLERA IN EGYPT.

THROUGHOUT Egypt during the week ending August 25th there were 2010 cases of cholera and 1520 deaths. At Cairo during that period 188 cases of cholera, with 164 deaths, were registered, as compared with 150 cases and 143 deaths during the previous week. The disease has spread to a great extent throughout both Upper and Lower Egypt during the week ended August 25th, notice having been received during this period of 144 new places which have become infected. Owing to this rapid extension of the epidemic the Director General of the Sanitary Department does not anticipate any marked improvement for some weeks to come. Dr. Ibrahim Eff. Hafiz, late sanitary inspector of Tala District (Menoufieh), contracted cholera during the execution of his duties and died on August 17th.

EDOARDO PORRO—IN MEMORIAM.

"BEFORE the next issue of THE LANCET," writes an Italian correspondent, under date Florence, Sept. 8th, "Salsomaggiore will have paid an impressive tribute to the Senator Edoardo Porro whom the 'Stazione Balnearia' has to thank for much of the organisation and development under which it has become known to the profession. There will be a 'Congresso di Ginecologia,' attended by distinguished obstetricians from both sides of the Atlantic and on the 11th a bust of Porro will be unveiled, the spokesman on the occasion being the Hon. Agostino Berenini, member of the Italian legislature. Among other speakers will be Professor Bertazzoli, lecturer on obstetrics in the Milanese Hospital, in whose hands the 'Sectio Cæsarea Salubrior Instituta' has had a success hardly inferior to that of the master."

PRESERVATIVES IN MILK.

TWO cases where preservatives had been used in milk were brought up at the Leigh (Lancashire) police court recently. In one of them Dr. Campbell Browne, the county analyst, found eight grains of boric acid to the pint of milk. Dr. J. King, the medical officer of health of Leigh, said that this was absolutely dangerous to an infant, and if it continued to take such milk it would be slowly poisoned; he also stated that a "preservative" even in small quantities retarded digestion. For the defence it was stated that "farmers had to sell their milk, and it went sour in summer much sooner than in winter," two very clear "glimpses of the obvious." It was urged that the farmers relying on the statement that such preservatives were harmless bought and used them without having the slightest idea that they were doing wrong As *these were the first cases of the kind brought before them* the magistrates took a lenient view and only ordered that the defendants should pay costs. The corporation of Leigh was complimented by the chairman of the magistrates for bringing these cases into court and he said that farmers should not be led away by plausible advertisements. It is to be feared that the standard of education attained by the average working farmer is as yet scarcely sufficient for his guidance in such matters.

THE DISTRIBUTION OF PLAGUE

A TELEGRAM from the Governor of Mauritius to the Colonial Office states that during the week ending August 28th there were 4 fatal cases of plague in the colony As regards Egypt, the weekly return issued by the Director General of the Sanitary Department states that from August 18th to the 24th there were at Alexandria 2 fresh cases and 3 deaths. The cases remaining under treatment were 8 in number all of them at Alexandria As regards Hong Kong a telegram from the Governor (received at the Colonial Office on Sept 9th) states that for the week ending Sept. 6th there occurred 1 fatal case of plague

THE PREVENTION OF SPITTING

WITH reference to the prevention of spitting in public—a subject with which we dealt in an annotation in our last issue—it may be of use to county councillors having the health and cleanliness of their localities at heart if we refer them to previous issues of THE LANCET[1] and call their attention to the action taken by certain Welsh county councils in this matter Under the Local Government Act of 1888 county councils are given the power to make by laws for the good rule and government of their county and a by law with reference to spitting has not only been drafted in the counties referred to by one of our Wales and Western Counties correspondents but has also been submitted to the Home Office for approval and sanction The proposed by law was as follows A person shall not spit on the floor of any public carriage or of any church, chapel public hall, waiting room, schoolroom, theatre, or shop, whether admission thereto be obtained upon payment or not." For the infringement of this by law a maximum penalty of £5 is provided The Home Secretary clearly did not think the by law *ultra vires* so far as the powers given to county councils are concerned, but he declined to approve of it as affecting churches chapels schools and shops Its application is thus to be limited to public carriages public waiting rooms public halls, and places of public entertainment, while the walls or sides of the places in question, as well as the floors, are not to be spat upon. It will be observed that no attempt has been made to include public highways or public houses, the by law dealing only with places where its enforcement is clearly within the bounds of possibility Even in the limited number of places enumerated above the principle upon which the Home Office sanctions the application of the by law is not quite clear but it would seem to be implied that certain places are more under private control than others and should be privately regulated. And in any case a conviction might be followed by an appeal as to whether the by law was a good by law under the Act notwithstanding the sanction of the Home Secretary As it stands however the existence of such a regulation in any locality even though with a limited application, should tend to call attention to the fact that promiscuous spitting without regard for others is at all times and in all places unnecessary, disgusting and insanitary

THE PREVALENCE OF SMALL-POX.

THE following figures show the number of cases admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned. On Sunday Sept. 7th, there was 1 fresh case, on Monday the 8th there were 4 fresh cases on Tuesday the 9th there were no fresh cases and on Wednesday the 10th, there were no fresh cases.

PULMONARY CONSUMPTION AMONG MINERS ON THE RAND

THE publication in THE LANCET of June 14th, p. 1677 of a paper on Gold Miners Phthisis in the Transvaal by Dr Thomas Oliver of Newcastle-upon-Tyne is receiving the attention of the authorities in South Africa which the important question deserves. It is announced from Johannesburg that a Government commission is to be formed which will probably be composed of State engineers doctors, mine managers miners and an explosives expert" to inquire into the causes of phthisis among miners The respirator it is stated is being submitted to practical tests and important information is being obtained. It is worthy of note that the appearance in our pages of the article alluded to at once attracted the attention of the *Mining Journal* one of the most important trade journals in this country and which for a few weeks in succession devoted considerable space to the discussion of the malady As far back as Nov 23rd, 1901 there appeared in the *Mining Journal* a letter on Rock Drill Miners, by Mr Nicholas Trestrail, C E Redruth who said It is surprising to see the number of men returning from foreign mines who in a comparatively short time continuously working rock drills are reduced from strong healthy individuals first to mere shadows and then death. Happily there is now the prospect of something being done for the Transvaal miners In our issue of Sept. 6th, p. 707 we published a letter entitled 'Gold Miners Phthisis, sent by Dr G A. Turner acting assistant medical officer of health for the medical officer of health of the Transvaal requesting medical men when reporting a case of death from this disease to notify the same to the public health department of the Transvaal and to add if possible the name of the mine where the deceased was employed As it is understood there are still some cases of gold miners consumption in the mining districts of *Northumberland* the *South African Government might* possibly receive some assistance from the north of England.

THE STUDY OF MENTAL FATIGUE IN SCHOOL WORK.

WE have received from Dr Giuseppo Biller of Bologna a monograph of much interest giving in detail the results of his investigations on an hour's work done by the children of public school The object of the inquiry was to study the amount of mental fatigue in a day's work and in the cycle of the year among boys and girls of an average age of 11½ years. The mental test used was the average correctness of arithmetical sums in division set in examination papers for an hour's work at the beginning and end of the school day and at the commencement and termination of the scholastic year The conclusions arrived at were that the quantity of work produced during each successive quarter of an hour affords no rule but becomes more inaccurate in the afternoon work is both less in quantity and worse than in the morning At the end of the school year work was always more in quantity but worse in kind. Mental fatigue in children has often been the subject of investigation and presents problems of interest, if the method employed in ascertaining the facts afforded a certain index of cortical exhaustion results might be obtained of great value in scientific education. Investigators mostly employ examination papers in arithmetic as tests, but the working-out of sums on paper requires work done in the brain and sight impressions with accurate *direction of the eyes* in looking at the figures, as well as expression of mental processes by the fingers in writing Some kind of control experiments are desirable to show what amount of inaccuracy in results may be due to the eyes and hand. An error in the written answer may depend upon not looking at the right figure, or writing down the wrong figure, or upon the mental processes in the cortex cerebri where impressions from sight of the figures should interact with impressions retained as to the arithmetical processes previously learned Inaccuracy appears often to depend upon retinal fatigue or irregular eye movements not under control. It would be a matter of interest, and might lead to more exact knowledge of the pathology of mental fatigue, if tests were employed in "mental arithmetic" where an auditory impression is followed in the brain by a mental process without necessitating accurate eye fixation so essential in working sums on paper The difficulty of investigating mental fatigue arises chiefly from the want of a quantitative standard of mental work, the correctness or value of the result is no necessary indication of the amount of nerve energy expended Superabundant spontaneous thoughts may cause delayed expression and mental confusion which is very exhausting

---

[1] THE LANCET March 22nd (p. 831) and June 28th 1902 (p. 1852)

BEFORE the revising barrister at Holborn on Sept. 8th Mr Waterson, on behalf of the President and Council of the Royal College of Surgeons of England, asked that their names should be reinstated in the lists He said that they had to his knowledge been included in the lists since 1892 and they were entitled under their charter to be there. Henry VIII. granted a charter to the "Masters and Governors of the Mystery and Commonalty of Barbers and Surgeons," and in 1800 George III. granted another Charter to the "College of Surgeons of London." This last retained all the old privileges of the original charter, including the franchise as freemen of the City of London and the suburbs The Franchise Act of 1832 retained those privileges of voting and the present claim was made under the Act. Mr Strickland said that he would give his decision after consulting the Acts of Parliament

OUR readers will be sorry to learn that Dr Enrico Bottini, professor of operative surgery in the University of Pavia, has been struck down by intracranial hæmorrhage, the right half of the body being completely paralysed At the last consultation held by his medical colleagues in attendance a slight improvement in the speech was found, while the mind had regained its clearness Dr Bottini's contributions to THE LANCET on Angioma Treated by the Galvano cautery are still remembered and cited, particularly abroad

WE are informed that Mr John Croft, F R.C S Eng, has resigned his appointment as one of the two medical officers of the National Provident Institution, a position which he has held for the last 18 years in association with Dr T Henry Green. We understand that the directors do not propose to fill the vacancy by the appointment of another surgeon in the place of Mr Croft but to select a member of the medical branch of the profession.

M DE SZELL, the Hungarian Premier, who is also Home Minister, has just issued a decree forbidding anyone except doctors of medicine to practise massage.

Looking Back.

Case of a Tape worm found in the Bladder, presented to the Royal Academy of Medicine at Paris, by M JULIA FONTANELLE

This case appears to us the more extraordinary, since in all our researches we have not been able to find a similar one It fell under the notice of Dr DARBON, celebrated for the various experiments which he made at the Hotél Dieu and La Charité for the expulsion of tænia. Before him several physicians had recognised the existence of round worms in the kidnies and the bladder GERON[*] has published a case of a woman passing three round worms by the urethra. TULPIUS[†] makes mention of a worm being passed with the urine, which was round, long, and red as blood. AMBRIOSE PARÉ[‡] says, that LOUIS DURET voided similar ones after a long illness PANZANI saw a clergyman fifty years of age, who suffered for four years constant pain in that part of the bladder which corresponded to the centre of the sacrum The different symptoms appeared to announce the presence of stone in the bladder, when there came away with the urine two lumbricales, after which the pain left him DUCERF,[*] CHOPPART,[†] DUMERIL,[‡] STROMAIER,[§] MOUBLET,[‖] and others have published similar observations. There is a curious fact recorded[¶] of a stone being formed in the bladder, having a worm for its nucleus. It is very probable that since the lumbricales are sometimes found in the bladder, the tænia may also exist in it, and the case communicated to the Academy by M FONTANELLE proves it. In this case several yards of tape worm were voided by a gentleman fifty-six years of age, his chief symptom was an insupportable pain at the verge of the anus, which left him after the worm was voided

Statement of Broussais' opinions

By M GOUPIL.

This is the seventh article which has appeared in this work, on the same subject. BROUSSAIS is the author of a work entitled *Histoire des Phlegmasies Chroniques* which contains much valuable information, conducts a periodical publication, the *Annales de la Médecine Physiologique*, and is the supposed author of a catechism of physiological medicine, written in a familiar style, being in the form of dialogues between a *savant* and a young physician, and this contains a succinct statement of the new medical doctrine, *as it is styled.* Opposed to this doctrine are several eminent men, who are, at present, carrying on a severe paper war with BROUSSAIS and his followers M. BROUSSAIS thinks that he sees gastro-enteritis in every disease, and consequently carries the anti phlogistic plan to an excess, thus laying himself open to the attacks of his enemies, who really withhold from him the merit which he deserves We shall take an opportunity of giving, at some future time, an account of the new medical doctrine

HOSPITAL SATURDAY.—The recent Hospital Saturday collection at Ilfracombe has resulted in nearly £250 being raised for the local medical institution.—In Haslemere, Surrey, Sept 6th was observed as Hospital Saturday, and by the collections a total of £26 was realised, which, after deducting 13*s* 6*d* for expenses, is to be distributed as follows Haslemere Cottage Hospital, £10 12*s* 6*d*, Surrey Convalescent Home, Seaford, £10 10*s*, and Royal Surrey County Hospital, Guildford, £4 4*s*

THE ELECTION OF A DIRECT REPRESENTATIVE TO THE GENERAL MEDICAL COUNCIL.

The following are the election addresses of Sir Victor Horsley and of Mr Joseph Smith —

SIR VICTOR HORSLEY'S ADDRESS.

To the Registered Medical Practitioners of England and Wales.

Ladies and Gentlemen —On the eve of the expiration of my term of office as one of your representatives on the General Medical Council I beg to offer myself for re-election.

After my first attendance at the Council I instituted a system of reporting to you at intervals the transaction of business in the Council

I need not, therefore, again recount the work accomplished during the past five years, but I may justly congratulate you on an improvement in the attitude of the Council towards the profession, and in its recognition if tardy *that reform and amendment of the Medical Acts is a* pressing necessity

My object in standing for re-election as a member of the Council is to further as much as I can the progress of those legislative changes which are not only under present social conditions essential to the welfare of the practitioner but are, in fact, also necessary to provide adequately for the work of the Council itself and to render its educational decisions properly effective.

I am obliged to you for the confidence you have reposed in me and will endeavour, if you re-elect me to fulfil as far as possible what I conceive to be the duties of your representative.

Cavendish-square, W Sept. 7th — Victor Horsley

MR. J SMITH'S ADDRESS.

To the Medical Practitioners of England and Wales.

Ladies and Gentlemen —On several occasions during the past six months I have been asked whether I would allow myself to be nominated as a candidate for the seat on the General Medical Council which shortly becomes vacant. I hesitated to give consent as I fully anticipated that some well known general practitioner in the north of England would have been nominated in order to assert the principle of Topographical Representation of which so much was heard during the election last year when Dr Woodcock of Manchester was a candidate In that case I should have stood aside altogether

Within the last few days several of my colleagues on the Central Council of the Incorporated Medical Practitioners Association have urged it upon me as a duty to offer myself as a candidate in order to give general practitioners an opportunity of declaring by their votes whether they are desirous that the seats given to the profession by Parliament, in response to the oft-repeated appeals of general practitioners, should like those granted to the corporations and universities be handed over to consultants. When the privilege of voting for members of the General Medical Council was first granted to us in 1886 the late Sir Andrew Clark, in a letter published in the medical journals said that the interests of consultants were already more than adequately represented and that it was natural and proper that general practitioners should elect as their representatives genuine working members of their own body " If he added, this principle of election be disregarded, it would seem at least to me that the fight had been fought and the battle won in vain."

Fellow Practitioners, to support and if possible with your help once for all to establish, the principle so forcibly laid down by the late Sir Andrew Clark, and, I may add subsequently endorsed by Sir Victor Horsley and other eminent consultants I have consented to be nominated. Of the 31 members of the Council there were only three general practitioners—viz. Messrs Brown and Jackson for England and Dr Bruce for Scotland. How much longer is this one-sided representation to exist?

With regard to my views on medical politics generally I am in *entire agreement* with my friends and colleagues on the Central Council of the Incorporated Medical Practitioners Association, Messrs George Brown and George Jackson (your present representatives on the General Medical Council) and if you do me the honour of electing me as your representative it will be my constant endeavour to work in harmony with them The voting papers will be issued in a few days and I regret very much that the short time which will elapse before you will be called upon to record your votes prevents me from placing my views through the post more fully before each elector I trust, however that the cause I represent, that of the general practitioner will be sufficient to induce every medical practitioner who reads this address to use his utmost endeavours to secure my return at the head of the poll

I remain, ladies and gentlemen,
Your obedient servant

Joseph Smith M.R.C.S. Eng L.M. L.S.A. Lond.
D P H Cantab.
Late President of the Incorporated Medical Practitioners Association
President of the Society of Members of the Royal College of Surgeons of England &c.

Bedford Park Chiswick Sept. 4th, 1902.

ASYLUM REPORTS

Hertfordshire County Asylum (Annual Report for 1901) —The average number of patients resident during the year was 528 comprising 229 males and 299 females The admissions during the year amounted to 125, of which number 74 were males and 51 females. Of these 124 were first admissions. Dr A. Norman Boycott the medical superintendent, states in his report that in only 42 cases among the patients admitted was the insanity the first attack and of less than three months average duration, and that in 57 cases the average duration of insanity on admission was over 12 months. These facts together with the advanced age of many of the patients, show that the type of insanity of the new cases was not very favourable as regards recovery " Among the admissions were 11 patients over 70 years of age. The number of patients discharged as recovered during the year amounted to 17 or 3·2 per cent. of the average number resident. The deaths during the year amounted to 33—viz., 20 males and 13 females or 6·02 per cent as calculated on the same basis The average age of the patients at death was 58·4 years. Of the deaths two were due to senile decay three each to bronchitis and Bright's disease, four each to colitis and organic brain disease five each to pulmonary tuberculosis and general paralysis of the insane and the rest to other causes No deaths were due to accident or violence and no inquests were held. Post mortem examinations were made in 31 cases The general health of the institution has been satisfactory During August and September there was an outbreak of colitis chiefly affecting old and feeble patient. No other disease of an infectious nature has occurred Owing to the epidemic of small-pox in London and also to the occurrence of cases in the neighbourhood of the asylum it was considered necessary in November to stop the visiting of patients by their friends. There have been no serious casualties during the year The Commissioners in Lunacy state in their report that the wards were bright clean, and cheerful that the dormitories were fresh and clean that the patients were neatly dressed and orderly in behaviour and that the medical case-books were intelligently and well kept. The committee of management states in its report that the main asylum buildings were completed during the year and that the wards were now occupied throughout the institution. An application was made to the Local Government Board for a loan of £2000 for the carrying out of the painting and papering of the asylum. The heating and lighting arrangements have worked well. A scheme for the disposal of the sewage has been prepared and application made to the Local Government Board for a loan of £2450 to carry out the said scheme The maintenance rate for patients per week was 14s. per head.

Obituary.

PROFESSOR RUDOLPH LUDWIG KARL VIRCHOW

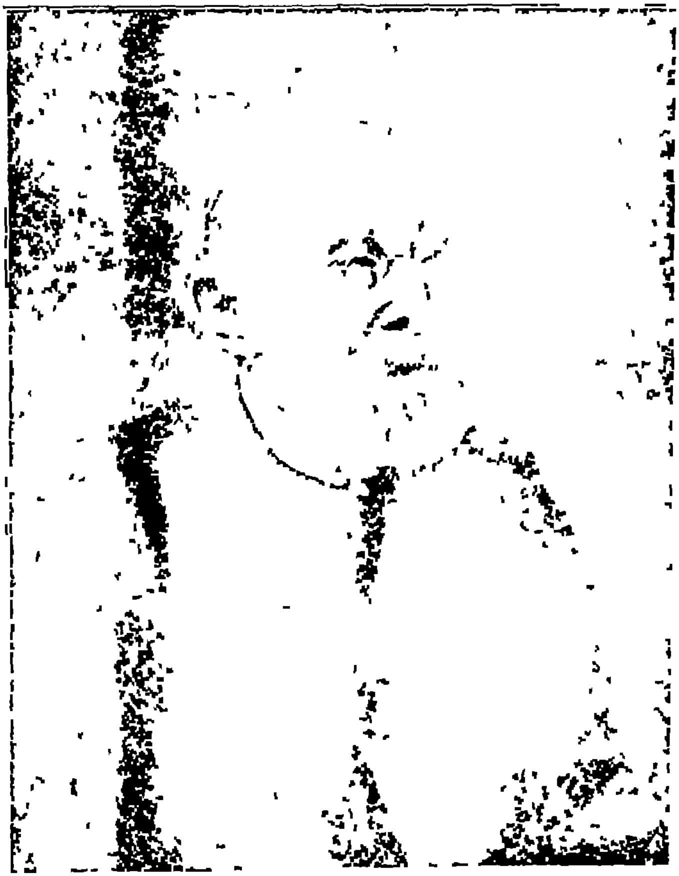
GERMANY and with her the entire scientific world, mourns the loss of Professor Rudolph Virchow who passed away on Friday last (Sept 5th, 1902) in the eighty-first year of his age. As a man of science he was world famous, and justly so even if his reputation depended on his "Cellular Pathology" alone, for by this epoch-making work, indebted though he was, in part at least, to the researches of previous observers, such as Schwann and his former teacher, Müller, he rescued the science of treatment from the stigma of empiricism and established it firmly upon the basis of a scientific appreciation of ultimate causes. As a democratic politician he represented to his countrymen the very spirit of progress and social reform, and as such his name will remain a cherished memory. So strenuous was his advocacy of his principles and so uncompromising was his language in the opposition to what he considered retrograde measures as to provoke a challenge from Count von Bismarck on the occasion of the defeat of the Government on a navy vote—a challenge which he happily possessed the courage to decline.

Although over 80 years of age Professor Virchow was in the habit of jumping on and off the tram cars whilst they were in motion and on the occasion of the accident, which occurred to him on Jan. 5th, he slipped on getting down and fell heavily in the road. He lost consciousness for a certain time but on recovering was enabled to give his name and address to a policeman by whom he was removed to his house. Professor Körte of the Urban Hospital was called in and found that Professor Virchow had fractured the neck of his femur. There was a great amount of shock present and for the first few days after the accident a fatal issue was expected, but Professor Virchow's constitution proved to be so excellent that he was soon in a fair way to recovery. Although advised to abstain from all mental work he was not a very tractable patient, and it is reported that he took so much interest in his own case that he declared that no osseous union would take place and that skiagrams which were taken proved the correctness of his opinion. After a time, however, he was able to get about on crutches and early in May he was removed to Teplitz with a view to try the effects of the hot springs which exist there. He improved so rapidly that after a few weeks' stay he was able to go to Hartzburg. A very inclement summer, however, prevented him from taking due advantage of the mountain air. He was nearly always compelled to keep his rooms and by and by symptoms of bodily and mental debility supervened. He became more and more apathetic, slept for the greater part of the day, and was unable to leave his chair. About three weeks ago his friends decided to take him home and although the journey from Hartzburg to Berlin takes only four hours it had a very bad effect upon him. He became unconscious and never really recovered from the coma, but expired on the afternoon of Sept. 5th. The news was received with the deepest sorrow by every class of the population of Berlin, and the Municipal Council, to which Professor Virchow had belonged since he went to live in Berlin, held an extraordinary meeting and decided that the funeral should be of a public character.

Rudolph Ludwig Karl Virchow was born on Oct. 13th, 1821, at the small town of Schivelbein, near Stettin, in Farther Pomerania. Of his early years there is but scant record; he appears to have received his education in the gymnasium at Cöslin, where he distinguished himself by his linguistic abilities. In addition to his knowledge of Latin, Greek, English, and French he was a good Hebrew scholar and selected that language as an optional subject for his *Arbiturienten* examination at the age of 18 years. He entered at the Friedrich Wilhelm Institut, a training college for army surgeons now known as the Kaiser Wilhelm Academie, in 1839, where during the next five years he studied under, amongst others Müller, Dieffenbach, and Caspar. In 1843 he proceeded to the degree of *Unterarzt* (Berlin University), presenting for his inaugural dissertation a thesis entitled, "De Rheumate Praesertim Corneæ." Although the students of the Friedrich Wilhelm Institut received their education on the condition of serving in the army, Virchow, during his career there, showed so much skill and intelligence that by order of the General Staff Surgeon he was released from active service and was given the place of assistant at the Charité Hospital. Selecting the scientific rather than the practical side of his profession he obtained the following year the post of prosector of anatomy to the Charité Hospital, acting as assistant to Robert Froriep whom he eventually succeeded in 1846. Early in 1847 he became external lecturer in pathology at the University of Berlin, and shortly afterwards founded the well-known *Archiv für Pathologische Anatomie und Physiologie, und für Klinische Medicin* in collaboration with Benno Reinhardt. From the time of his colleague's death in 1852 onwards he continued to edit the journal alone and enjoyed the satisfaction of celebrating its jubilee, together with that of himself as a teacher, at a banquet held in the Kaiserhof in December, 1897.

In 1848 an incident occurred which would have proved the undoing of a weaker man. Selected to accompany the medical officer entrusted with the investigation of a severe epidemic of relapsing fever (*hunger typhus*) in Silesia, the actual investigation and the preparation of the report thereon devolved upon Virchow and these duties were carried out in the masterly style characteristic of the man. In his "Mittheilungen uber die in Oberschlesien herrschende Typhus epidemie" he denounced the evils from which the disease resulted, demanded extensive reforms, and concluded by stating that nothing short of the extension of the benefits of civilisation to one and a half million living souls would successfully cope with the epidemic. Such reflections upon the ineptitude of the then administration, coupled with the fact that Virchow on his return had allied himself with the ultra Radical party and had founded in association with Leubuscher a medico political journal, *Die Medicinische Reforme* (a paper that ceased to exist when Virchow was appointed to Würzburg), were amply sufficient to ensure his dismissal from all his professional posts in Berlin. His fame as a pathologist had, however, already spread beyond the confines of the capital and the University of Würzburg at once seized the opportunity and offered Virchow the professorship of pathology and the directorship of the newly founded Pathological Institute. These posts were accepted and for the next seven years Virchow devoted himself almost completely to research work, contributing many valuable memoirs to the pages of his *Archives* and founding a school of workers and thinkers the results of whose observations cannot be too fully appreciated. In 1855 he commenced the publication of his best-known work, "Die Cellularpathologie in ihrer Begrundung auf Physiologische und Pathologische Gewebelehre," propounding therein, as the basis of his theories, the now familiar dictum, "*Omnis cellula e cellulâ*."

On the death of Professor Hemsbach the Faculty of the University of Berlin petitioned the Minister of Public Instruction to offer a chair of pathology to Virchow, and in spite of strong and bitter political opposition the appeal was successful and Virchow returned to Berlin. He accepted his appointment on the condition that a pathological institute should be founded, and the Government agreed to his wishes. Soon after his return to Berlin the first complete edition of his "Die Cellular Pathologie" appeared in 1858. His great work on new growths, unfortunately never completed, also dates from this period. Under his direction the pathological department, formerly the dissecting room, of the Charité Hospital became a model for similar institutions. With indefatigable zeal he collected specimens of pathological conditions and arranged and classified them till he had got together a collection only to be equalled by the Hunterian Museum in London. One of his greatest satisfactions was when two years ago, on the occasion of the rebuilding of the Charité Hospital, he was able to open the Pathological Museum where his collection had finally found adequate room and was therefore made accessible to students and to the public. Besides this pathological museum he had made a large anthropological collection of his own, consisting mainly of crania of the different human races. Notwithstanding his manifold occupations he delivered his lectures regularly, and his assistants were only allowed to replace him for the practical work in microscopic anatomy and in making dissections. His lectures were attended not only by students but by medical men from every part of the world. He was not an orator in the usual sense of the word, his voice was weak and his



PROFESSOR RUDOLPH LUDWIG KARL VIRCHOW.

speech was simple and without that power of carrying away an audience which is so common among French speakers but when he was once upon the platform of the lecture room everybody felt that the little man with the sharp grey eyes was one to be listened to with the utmost attention After a few years spent in quiet work Virchow again entered public life as a member of the Berlin Municipal Council with which body he was connected as an active member for a period of over 40 years. In this capacity his powers of organisation and his conception of the duties of the State with regard to the well being of the people are evidenced by the establishment of the hospitals of Moabit and Friedrichshain and the lunatic asylums of Dalldorf and Lichtenberg His greatest work, however in practical hygiene was concerned with the introduction of drainage and in the erection of sewage-farms, hygienic improvements which he was enabled to carry out despite the opposition and the want of judgment displayed by a great part of the population and even by the authorities. Some doubts were expressed whether the soil of Berlin and its neighbourhood were fitted for a system of sewerage and a sewage farm Experience, however has shown that Virchow's genius was right in insisting upon it, as since the establishment of the system Berlin has become one of the healthiest towns on the continent enteric fever scarcely ever prevailing Virchow's hygienic work is closely connected with his political career. He was, as we have already stated, early elected a member of the Municipal Council and this position enabled him to carry out in a practical manner what he had found by theoretical and statistical studies to be the best for the health of the town. In 1862 he took his seat in the Prussian Diet and by sheer ability was soon recognised as the leader of the Radical party This position he resigned however, in 1878 and in 1880 he became a deputy of the Imperial Reichsrath As leader of the Opposition he did yeoman service for his country though his frequent conflicts with the Government prevented any of those decorations which are occasionally bestowed even upon scientific men falling to his lot

In 1866 his untiring energy found another outlet in the organisation of the ambulance service for the army both in that campaign and in the *succeeding one of* 1870–71. *Pathology* and politics, however were insufficient to fill the life of this remarkable man. He was President of the German Geographical Society and the Society of Anthropology and Ethnology (of which he was one of the founders) and of many others. Archæology and Egyptology also claimed place in his multitudinous interests and it may truly be said that in whatever branch of science he worked he became an acknowledged authority Honours of all kinds were showered upon him. In 1874 he became a member of the Royal *Academy of Science of Berlin. On the occasion of the* centenary of the Institut de France Virchow was made a Commander of the Legion of Honour and in the following year he became a Foreign Associate of the French Academy of Sciences. In 1893 Virchow visited England and delivered the Croonian Lecture of the Royal Society, a full report of which will be found in THE LANCET of March 18th 1893, p. 671, it was delivered in English, the subject being The Position of Pathology among the Biological Sciences.' The discourse, which shortly showed the steps by which Virchow had *felt himself able to give utterance to his famous* dictum, *Omnis cellula e cellula* was a masterly exposition of the progress of pathology from the time of Harvey Some six months previously the Royal Society had honoured both itself and Virchow by awarding him the Copley medal a distinction of which he himself said ' Its significance far exceeds the distinctions which the changing favour of political powers is accustomed to bestow " It was awarded for his investigations in Pathology Pathological Anatomy and Prehistoric Archæology

He visited London again in 1898 and gave the Huxley Lecture at the Charing Cross Medical School on the Recent Advances in Science and their bearing on Medicine and Surgery a lecture that impressed his hearers with the fact that advancing years had not blunted either his keen enthusiasm or his comprehensive grasp of detail. The lecture was delivered on Oct. 3rd and on the 5th Virchow was entertained at dinner at the Hotel Métropole by the members of the medical profession of Great Britain and Ireland. Lord Lister presided but Sir John Simon, Sir James Paget, and Sir Thomas Grainger Stewart were unavoidably absent. Of these three Sir John Simon alone remains to us the other two having passed away It was upon this occasion that Sir Samuel Wilks, the President of the Royal College of Physicians of London, said that he remembered the time somewhere about 40 years before when he was beginning to study the subjects which Professor Virchow had so advantageously taken up. He and his contemporaries were groping their way in the dark when a light came upon them suddenly from afar—a light which illuminated everything and penetrated into the interior and gave them a new insight into physiology and pathology Virchow came to generalise like another Newton and gave them the Principia of medical science.

With advancing years every occasion was taken of expressing to the *Altmeister* the affection and appreciation of contemporaries and pupils alike. Thus in 1891 his seventieth birthday was celebrated and a gold medal was presented to him by his Emperor in recognition of the immense services which he had rendered to science in 1893, the fiftieth anniversary of his doctorate and again in 1897 the jubilees of his first teaching appointment and of the foundation of the *Archives* were made the subjects of sincere and hearty rejoicings whilst on the occasion of his eightieth birthday—only last year—delegates from practically all the civilised countries of the world assembled in Berlin to do him honour

In the space at our disposal it is utterly impossible to attempt anything like a list of Virchow's contributions to scientific literature or of the various honours of which he was the recipient Suffice it to say that his active work ceased only with his death—the world's appreciation of his worth remains.

We hope next week to refer to the influence of Virchow as a pathologist upon that science which he has made his own, but we may say here that by his researches into the nature and causes of death he has let into the secret chambers of life a certain amount of light. It is to the patient work of men like Virchow and Pasteur among the dead and of Lister Ehrlich and Van t Hof among the living that we may apply the words of Crookes In old Egyptian days a well known inscription was carved over the portal of the temple of Isis I am whatever hath been is, or ever will be and my veil no man hath yet lifted Not thus do modern seekers after truth confront nature—the word that stands for the baffling mysteries of the universe. Steadily unflinchingly we strive to pierce the inmost heart of nature, from what she is to reconstruct what she has been and to prophesy what she yet shall be. Veil after veil we have lifted, and her face grows more beautiful, august, and wonderful with every barrier that is withdrawn.

On Tuesday Sept. 9th, the body of Virchow was laid to rest in the cemetery of St. Matthew The first portion of the burial service was said in the Rathhaus where the remains had lain overnight. The hall was draped in mourning and over the platform for the speakers hung a crucifix The Prussian Ministers of Education and of Finance were present together with Professor Mommsen Professor Harnack, and Professor von Bergmann. Professor Waldeyer and others delivered orations and the procession which was over a mile long then started on its journey to the cemetery

---

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced —*Dr Pasternatski, Professor of Internal* Medicine in the Military Medical Academy St. Petersburg — Dr von Tappeiner the Nestor of the profession at Meran, at the age of 86 years He was an authority on anthropology and botany with special reference of course to the Tyrol.—Dr Luis Rodriguez Seoane, Professor of Therapeutics in Santiago.—Dr. Paul Plosz, Professor of Medical Chemistry in the University of Budapest at the age of 57 years. He published a Hungarian translation of Hoppe-Seyler's Physiological Chemistry having been his pupil —Dr A. von *Rommert, Honorary* Body Physician to the Czar and Inspector General of the Medical Department of the Russian Army

---

DEVON AND CORNWALL SANATORIUM FOR CONSUMPTION.—The sanatorium committee of the Devon and Cornwall Branch of the National Association for the Prevention of Consumption and other *Forms* of Tuberculosis announces that £4967 have been received towards the purchase of the Didworthy estate on Dartmoor which the committee has acquired and is fitting out as an open-air sanatorium for consumptive patients

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR THE YEAR 1900-1901[1]

THIRD AND CONCLUDING NOTICE.[2]

IN the second notice of this report mention was made of some curious points which are to be found embedded in the vaccination statistics, and attention was called to the more important special inspections which were undertaken in various parts of the country to determine the sanitary condition of places which had suffered from visitations of preventable disease or in which obvious defects in sanitary administration had been brought to the notice of the Local Government Board

The possibility that the plague might be readily introduced into many parts of England and Wales and the knowledge previously acquired by the Board that in many ports the sanitary administration was defective and that there was a risk that incoming ships might not always be examined with due care led the Board to cause a general survey to be made of the chief ports and riparian districts

It is beyond doubt that these surveys have produced the most beneficial results. The visits were made in the years 1897-98-99 and 1900 Dr Theodore Thomson's report (Appendix A, No 20) shows that 40 port sanitary districts, 14 urban riparian districts, and three rural riparian districts were examined during these years. During the "cholera survey" which was made in 1893 and 1894 60 ports, 31 urban riparian districts, and six rural riparian districts were examined. A classification has been made of the results of the reports, the places visited being arranged under three headings (1) good or satisfactory, (2) fair or moderate, and (3) lax, *unsatisfactory*, or bad In the case of the examinations made as to the condition of vessels coming into port the ports and riparian authorities have also been classified into three divisions according to their efficiency or their lack of efficiency It will be seen from the table given below that there has been a *distinct* general improvement in the condition of the ports between the dates of the "cholera survey" (1893-94) and of "plague survey" (1897-1900)

Table showing in the Case of 50 (identical) Districts Visited in the Course of the Plague and the Cholera Surveys respectively the Manner in which Sanitary Affairs were Conducted by the Local Authorities

Quality of administration	Plague survey Number of places	Cholera survey Number of places
Class I, Good ..	21	15
Class II Indifferent	13	14
Class III, Bad ..	16	21
"Extent and quality of inspection of vessels coming into port.	—	—
Class I Good	18	14
Class II Indifferent	16	14
Class III Bad	16	22

The most important places in which improvements have taken place are the River Blyth *port sanitary* district, Dartmouth, Southampton, Workington, and Great Yarmouth. The state of Portsmouth is still unsatisfactory, that of Newhaven is very unsatisfactory, the state of Dover and of Holyhead is bad. The large amount of passenger traffic from the Continent to Dover and Newhaven renders the maladministration of these places a matter of serious concern

The summary of the history of the *progress* and diffusion of the plague in 1900 (Appendix A, 18) is a continuation of that which was contained in the annual *report* for 1899 The two reports together form a valuable digest, but the absence of references to the original sources of information certainly seriously detract *from* its use as a work of reference—a matter for especial regret in view of the enormous amount of labour which must have been bestowed on its production. In addition to this summary Dr R. Bruce Low has drawn up a memorandum on cases of plague and "suspected plague" in England and Wales during the year 1900 and on the precautionary measures adopted to prevent the importation and spread of the disease This report cannot fail to be of use to the future historian of plague, but it would serve no useful purpose to recapitulate in this place the information on a subject which was fully dealt with at the time in the columns of THE LANCET It may not, however, be out of place to say that the efficiency and energy displayed by the medical officers of the Local Government Board form a very pleasing contrast to the lack of those qualities lately shown in other departments of the State

The reports on the auxiliary scientific examinations contained in Appendix B are of great interest and some of them are likely to be of practical benefit to the community at large Appendix B, No 1, is a report on the behaviour of specific microbes in relation with cereal products, by Dr E Klein and Dr A C Houston The report is illustrated by a number of well produced plates The results are of a reassuring character Wheat, flour, oatmeal, and ground rice were the substances with which experiments were made, the bacilli of typhoid fever and of diphtheria and the vibrio of cholera were the microbes of which the behaviour was watched The result was briefly that in no single instance was there observed any tendency on the part of any of these microbes to multiply in the medium to which they were added

Appendix B, No 2, is a report on the bacteriological analysis of various foodstuffs by Dr Klein The substances which were subjected to "bacterioscopic" analysis in search of specific microbes were milk, butter, margarine, tinned substances, and other varieties of preserved food On the whole the results of these experiments will prove comforting to those who eat such things as tinned salmon, tinned potted ham, German sausages, and black puddings. It is rather to be feared, however, that those who have a partiality for delicacies of this description rarely heed the reports of scientific investigations.

The third inquiry in which Dr Klein was engaged (Appendix B, No 7) had regard to the infection of mussels and cockles with the typhoid bacillus and with Koch's cholera vibrio The results of the laboratory experiments on these questions are somewhat disquieting It appears that Koch's vibrio flourishes and probably increases in the substance of the oyster The typhoid bacillus is also able to support existence in the bodies of mussels and of cockles It is true that boiling water kills the microbes as well as the bivalves but Dr Klein has collected evidence to the effect that they are sometimes eaten raw, and he denies what he calls the "validity of the cooking" to which they are customarily submitted. He has performed experiments in imitation of the form of cooking to which he takes exception, which it seems consists in pouring water on a heap of the bivalves The boiling water, he found, was readily cooled by coming in contact with the upper layers of a basin of mussels and those in the lower layers still contained living typhoid bacilli. The very obvious lesson is, that those who eat mussels and cockles should ensure that they are sterilised by heat It may possibly be worth while to add that there is a general consensus of opinion on the part of those who eat mussels near some of the places from which they come that they are unfit for food at certain seasons of the year and they are, in fact, not then eaten at these places Whether this opinion is or is not well founded there is, of course, no doubt that all the ill-effects due to the eating of mussels are by no means to be ascribed to typhoid fever That question, however, is not the one in which Dr Klein was concerned, and it may be hoped that the results of his work will cause an improvement to be effected in the cooking of mussels Possibly the Local Government Board will issue a memorandum to peripatetic mussel merchants insisting on the necessity for the adequacy of the method of cooking to be adopted,[3] otherwise it seems likely that Dr Klein's investigations will have little practical result. Of the other reports one by Dr M. H. Gordon on the Bacteriology of Scarlet Fever (Appendix B, No 3) gives the result of his further researches into this subject

In reference to this investigation it may be well to recall the fact that the last report issued by the medical officer of the Local Government Board contained the account of investigations into the bacteriology of scarlet fever which had previously been made by Dr Gordon. A summary of the conclusions at which he arrived has already been given in The Lancet [4] It may be stated briefly that they supported *the view that the streptococcus scarlatinæ is the specialised* and essential agent of the specific infection known as scarlet fever In a footnote to his report Mr W H Power stated *with his usual scientific caution that the question as to how* far the streptococcus scarlatinæ merited the epithet specific" was a matter for future investigation to decide and that for the present the term was better avoided. As a result of his further studies Dr Gordon is led to infer that the more grave manifestations of scarlet fever are due to more than one cause. He believes that ' the infectious malady scarlatina," is due to the agency of streptococcus scarlatinæ and that ' the dangerous phases of the disease frequently result from the invasion of the tissues and of the blood of the patient by the streptococcus pyogenes These two organisms have been put to the most severe biological tests. Each of them," says Mr Power derived in turn from a variety of sources has been passed through the bodies of a series of rodents and very generally with the result that when recovered from the tissues of the last rodent of the series the particular streptococcus has been found to have retained its biological individuality altogether unimpaired. Mr Power believes that as a result of the whole series of Dr Gordon s investigations there is hope that in future indications for the satisfactory treatment of scarlet fever may be obtained by means of bacterial differentiation. It is to be hoped that this sanguine view may prove correct but, be this as it may, Dr Gordon s paper is worthy of study and of consideration.

[1] Thirtieth Annual Report of the Local Government Board, 1900-1 Supplement containing the Report of the Medical Officer for 1900-1 London: Eyre and Spottiswoode. 1902. (Cd 747 Price 6s)

[2] The first and second notices were published in THE LANCET of August 23rd (p 548) and Sept 6th (p 695) 1902.

[3] Dr Klein could doubtless draw up a set of regulations to ensure proper cooking

A series of experiments of still greater practical importance was undertaken with a view to elucidate the etiology of enteric fever and the biology of the soil. Of the problems on which information was sought the first was What are the precise conditions which in a surface soil otherwise favourable to the multiplication of the typhoid bacillus determine its prompt extinction when placed therein in competition with the bacteria natural to the soil? On this question Dr Sidney Martin, F R.S. made a series of experiments (Appendix B, No 5) in continuation of his previous researches on the question The chief results which he had hitherto obtained have been published as appendices to the report of the medical officer of the Local Government Board and they may be briefly summarised as follows (1) In certain virgin soils the typhoid bacillus neither grows nor lives, (2) after cultivation these soils become capable when sterilised" of maintaining the typhoid bacillus for a limited time (3) cultivated soils—that is to say soils containing organic matter— when sterilised support the bacillus for a long period and the bacilli spread through the soil (4) unsterilised cultivated soil—or in plain language, ordinary garden soil—is inimical to the bacilli, the micro-organism cannot be obtained from such soil after 12 days or so. As a result of his further studies Dr Martin finds that the typhoid bacillus requires nitrogenous food. When proteids are present in the soil they are very slowly exhausted and they enable the bacillus to live for a considerable time. Some of the bacteria which live in the soil he believes, cause the disappearance of the typhoid bacillus. Dr Martin is of opinion that it ought not to be inferred that the putrefactive bacteria cause the death of the typhoid bacilli by destroying the nitrogenous matter and so exhausting the nutrient medium, or to use more simple language, by starving them out. Experiments have shown very definitely " he says, that the products of putrefaction soluble in alcohol are very powerful agents in inhibiting the growth and in destroying the vitality of the typhoid bacillus " The bacillus, he maintains is destroyed by the products of the putrefactive bacteria which exist in most cultivated soils. The chief and practical point which is taught by these investigations is that the typhoid bacillus has usually only a short life in the soil.

Another question on which Mr Power thought that inquiry should be made was as to how far the hostility exhibited in the laboratory by surface-soil microbes towards the typhoid bacillus is under the natural condition of the open country extended to other microbes of intestinal derivation to such microbes, for instance as are found in far greater number in sewage than is the typhoid bacillus and which under the conditions of open country experiment are much more readily identified and estimated in bulk than is the enteric fever microbe. The clear way in which Mr Power propounds definite problems for his scientific staff to solve must have, and indeed has already produced a most salutary effect on the usefulness of the work of the department by directing it in the course most likely to be useful. Dr Houston who was *entrusted with this investigation as a result of his elaborate* experiments has come to the conclusion that the bacteria of the soil taken as a class readily gain the mastery over the sewage bacteria (Appendix B. No. 4). In regard to the bacillus coli of typical character he found that it survived only a short time in the soil. But this microbe occurs in atypical forms or as Mr Power, using a well known botanical expression, happily names them, ' varieties. ' These varieties of the bacillus coli appeared to become extinct but on several occasions a distinct increase in their number took place and during this time of increased vitality typical" forms of the microbe were again present. On one occasion it appears that they were found on the fifty sixth day and on another as late as the eightieth day after the bacilli were put into the soil

A third question on which definite knowledge was wanted was What in a given locality the soil of which has long been habitually fouled by excremental matter and wherein enteric fever is endemic, is the result, as far as the bacterial quality of the deep soil water of conflict in the upper layers of the soil between micro-organisms proper to the soil and intestinal bacteria with which such soil has been fouled? An investigation in order to elucidate this question was made by Dr Houston at Chichester which is a city in which as Mr Power truly observes, the conditions of soil fouling could be considered to answer the required purpose. Dr Houston examined water from 14 wells the majority of which were situated in those parts of the city which are considered to be endemic typhoid fever areas 30 samples of well water were tested in regard to their chemical purity the presence and relative abundance of the bacteria capable of producing gas in gelatin shake-culture of the bacillus coli of the bacillus typhosus of spores of bacillus enteritidis and of streptococci. The results of chemical examination were not such as to give rise to suspicion of organic pollution on the contrary they indicated somewhat exceptional purity ' The number of microbes found was small Coli like microbes were found in 22 out of the 30 wells. The typhoid bacillus was not detected

The length of a statement of the final conclusions ' of a scientific paper is usually inversely proportioned to their importance. The results of the surface soil on intestinal bacteria have been briefly stated. The investigations on the water of Chichester Dr Houston suggests amongst other final conclusions, may lend some support to the tentative hypothesis that soil plays some part in fostering and localising enteric fever" in Chichester Mr Power it may be observed does not adopt that hypothesis nor does he suggest the view that the eight final conclusions given in the report exactly answer the one somewhat exhaustive question which he propounded Dr Houston deserves the greatest credit for the laborious investigation which he has carried out, but it must be admitted that the insanitary condition of Chichester requires further study

The last of the reports (Appendix B, No. 8) of this series, which is by Dr J S Haldane is a preliminary note on the use of carbonic oxide in destroying rats on shipboard This investigation was undertaken in view of the fact that rats on board ships arriving from plague-infected places were not unlikely to become sources of danger in this country The way in which to exterminate such rats within a short space of time and without injuring the cargo of the vessel was a problem of some difficulty Carbonic oxide was the gas chosen by Mr Power for the experiments and this for two chief reasons In the first place it was evident that it could be introduced into a vessel before the cargo was broken " or moved, and therefore before the escape of any rats could be effected In the second place as it was already known that the gas stupefies rats without alarming them it appeared therefore unlikely that any of them would attempt to jump overboard when they were submitted to the fumes additional advantages offered by the gas were the absence of smell and the fact that the ship's fittings and cargo would not be damaged by it. The use of carbonic oxide for the disinfection of ships is indeed by no means a new one, for it has long been the practice to kill the rats which infest the holds of empty ships by lighting a charcoal fire and closing the hatches The first point which Dr Haldane had to settle was the method by which the carbonic oxide should be obtained Having rejected the use of coal gas and water gas because of the danger of explosion, he adopted the use of a gas called "producer" which consists chiefly of nitrogen and carbonic oxide "Producer," is obtained by blowing air through a deep bed of incandescent coke or anthracite contained in a specially devised furnace[5] The gas is purified to eliminate the smoke and the sulphuretted hydrogen which are formed in the process of manufacture This is necessary because the latter gas would injure paint, tarnish metal work, and injure certain cargoes. Experiments with the gas generated on a barge and introduced through the window of a house-boat speedily caused the death of rats contained in cages which had been placed in various parts of the boat. Diagrams of the apparatus used for the manufacture and for the purification of the gas are given in the report, which, as Mr Power says, clearly shows that the method pursued was wholly satisfactory "so far as an empty vessel of small size is concerned" An investigation is now being made to determine whether it is equally efficient in the case of vessels in which the cargoes are intact.

[4] The Lancet June 22nd 1901 p 1779

THE TRANSACTIONS OF THE BRITISH CONGRESS ON TUBERCULOSIS, 1901[1]

(Concluded from page 700)

WE come now to the consideration of the proceedings in the

SECTION OF PATHOLOGY

There is an impression left after reading the proceedings of this Section that much of the study of tuberculosis has left the human body and branched into the paths of biology, morphology, and animal pathology Including the discussion on tuberculin three days out of four were employed in this direction Dr Moeller gave a most succinct and lucid sketch of the bacilli that stain like tubercle and recounted the cultural and disease producing characters of nine bacilli other than the bacillus tuberculosis. Some of these may come to resemble their precursor even in both respects, but it is reassuring to discover that time and temperature of a culture growth remain a good test of the tubercle bacillus, that the microscope can unravel pseudo tuberculosis, and that none can vie in malignancy with the bacillus of tubercle. The profound and numerous investigations of Dr Moeller are those not only of a pathologist but of an experienced clinician It is of value to learn from him that while the bacillus will continue to hold its high place in diagnosis we must be on our guard in deducing tubercle from but one or two bacilli in the sputa or in the urine, for, in gangrenous lung particularly, the butter bacillus may be found and the smegma bacillus might lead to false suggestion of urogenital tuberculosis

An English bacteriologist, Dr W Bulloch, has closely studied the acid fast bacilli and his contribution to the discussion travelled fully over the ground of vegetable morphology, recounting the investigations of those who have studied the departure of the bacillus from the true bacillus form into the filamentous form and further into the actinomycotic form, the variation in cultivating media from a serum medium up to acclimatisation of the organism to a luxuriant growth on proteid free media, and the meaning of the staining properties first shown by Ehrlich. This last is shown to be due to a body of the nature of wax which constitutes 43 per cent. by weight of dried bacilli

Mr Harold Swithinbank showed in the museum the results of many years' work in growing these acid fast bacilli on a medium of constant composition The approximation of character after many generations naturally tempts the onlooker to think that their identity may be proved Neither Dr Moeller nor Dr Bulloch has seen any evidence of transmutation from one form to another, from saprophyte to parasite Nor did this great issue receive elucidation It is to be hoped that Mr Swithinbank's cultures will go through tests for their infectivity, whatever the result it would pave the way for further investigations

A paper on the Infectivity of the Milk of Tuberculous Cows, the Bacteriological Diagnosis, and the Practical Value of Tuberculin for the Extirpation of Tuberculosis among Cattle, read by Dr Lydia Rabinowitsch,[2] must have brought home to her audience the practical issues of acid fast bacilli. The microscope alone is untrustworthy, Kühnau having found that from 20 to 25 per cent of the cases examined showed acid fast bacilli, not tubercle bacilli. Dr Rabinowitsch tested infectivity by the intra peritoneal injection of guinea-pigs, in her opinion the only and safest proof of tubercle. Many and tedious experiments were made and the Section was informed of the great difficulties of pronouncing upon the presence of tuberculosis of the udder and of the presence of infectivity when diagnosed, the inference being made that the tuberculin test was the sole quick and sure method. Dr Ravenel stated that this was done in Philadelphia for "notified milk," at least two tuberculin tests during the year being depended upon to keep the milk good Professor Bang commented on the fact that tuberculin would not show whether the disease was of the udder or elsewhere Professor Adami recounted instances where tuberculosis was experimentally produced by the inoculation of centrifugalised milk from cows in which no definite tuberculosis of the udder was present Professor D J Hamilton suggested that evidence of a calf being infected without disease of the udder being present would be much to the point. The facts or arguments brought forward at the Congress must certainly receive due consideration by a medical officer of health before he brings his evidence about milk into a court of law, and he will no doubt desire fair evidence of tuberculous mammitis and will not be content with the presence in the milk of a few acid fast bacilli only

It was an admirable arrangement of the Section to devote a day to morbid anatomy and histology—"The Varieties of Tuberculosis"—and still more so to invite Professor Benda to open the discussion

Professor Benda's paper was replete with facts of pathological anatomy precisely worked out and arranged He absolutely abstained from any divergence into paths of speculation. Immobility, slow growth, and severe reaction are the fundamental properties of the bacillus The spread was traced by Koch essentially to the wandering cells but all paths available are made use of. Where masses of tubercle most commonly occur, in the lung and kidney, the epithelial canals play the most important rôle and they may play such part even when infection is conveyed by the blood stream primarily The mode of spread was fully described, the small bronchi are the most important parts affected, expiration and inspiration are equally agents of spread, but infection does not follow everywhere seeing how many bacilli pass through the larynx before tubercle occurs there In the kidney the spread is less in the convoluted tubules which are soon blocked, checking progress The spread is greater in the medullary portion, where affection of the straight and collecting tubes marks the site of mischief, when the gland ducts are deluged spread can occur above and below If a muscular tube like the ureter is blocked antiperistalsis will occur and this accounts for the unusual occurrence of a spread of disease from the bladder upwards. Professor Benda accounts the lymphatic system a less frequent means of spread He describes in the intestines the leucocytes carrying bacilli to the lymph ducts and glands, the blocking of ducts, the sure termination of infection, by the gland at least, unless the glands become infected themselves throughout, then bacilli appear beyond them and the thoracic duct, and finally the blood stream can be infected The greatest interest attaches to his description of the blood stream as an agent of spread In 1894 owing to improved histological methods of studying the structure of the walls of the blood vessels, their participation in tuberculosis was early shown by Rieder Professor Benda then saw tubercle of vessels for the first time and since he has been astonished at the amount he can discover The small vessels if affected are quickly blocked It was to the larger arteries and veins, by a tuberculous focus upon their wall, that Weigert first traced back with complete explanation the spread of a general infection. Professor Benda shows further that by tuberculous metastasis in the intima an infection of the vessel wall results. This may be primary or engrafted on an already damaged intima; it may occur upon the thrombi of an atheromatous aorta An enormous outbreak may arise in tuberculosis of the cardiac valves. Infection is not a necessary sequence of tuberculosis of the intima of large vessels fibrinous coagulum may effectually seal it. It is to be regretted that no translation of this paper is given, not even is the translated epitome reproduced.

---

[5] The exact composition of the gas was found to be carbonic oxide, 27 61 hydrogen 4 18 carbonic acid 3 75 sulphuretted hydrogen, 0·07 nitrogen, 64 39.

[1] Transactions of the British Congress on Tuberculosis for the Prevention of Consumption London July 22nd to 26th 1901 Vols i to iv Edited by the Honorary Secretary General London: William Clowes and Sons, Limited 1902.

[2] THE LANCET, Sept. 28th, 1901, p 838

Professor R. Muir pointed out at the end of the discussion that a broad view had been taken and the mode of entrance and the distribution of the bacilli formed the main exposition of the subject. From our knowledge of those points there issued clinical light the absence of a tuberculous lesion from the intestine does not mean that bacilli have not entered through the mucous membrane, nor does a pulmonary lesion indicate that the lesion was produced by inhalation. Several speakers upon this latter point gave evidence how in children especially the bacilli often spread from the glands of the lung into the lung substance and the pulmonary infection was thereby a secondary one.

Professor W Osler valued highly Professor Benda s observation that in acute miliary tuberculosis an enormous number of bacilli growing directly into tuberculous endarteritis can be a cause of profound toxæmia so this profound local toxæmia and not the mass of tubercles will adequately account for so-called typhoid forms of acute miliary tuberculosis.

Professor Hamilton gave a reflective review of the seat of election of tubercle bacilli, their rapidity of absorption and degrees of virulence. The most prominent path of distribution was considered to be the lymphatics. The general diffusion of the disease was held to depend upon the rapidity of absorption by the blood vessels such absorption being conceived to occur where the abundance of the bacilli overwhelms the phagocytic resistance of the blood. The relative frequency of lymphatic channels as the path of diffusion was explained by the relatively low resistance offered by the lymphatic phagocytes compared to those of the blood stream. The proclivity of lymphatic glands bone marrow and spleen for tubercles, it was suggested, might be explained by the mechanism of the circulation in these cases affording a simple winnowing action; at the same time it was pointed out that, while such action in the capillaries of the liver arrested particulate foreign matter that organ was remarkably free from tubercle. The immunity so frequent in the pericardium when neighbouring serous membranes may be severely affected suggested that the pericardial serum was detrimental to the bacilli Professor Hamilton supported the general impression that the absorbents can pass on bacilli from the mucous membrane without that structure becoming itself tuberculous

Dr S H. Habershon s large experience of the post-mortem manifestations of phthisis was valuable but his researches were of necessity less fully analysed than the researches of previous speakers. His impressions differed from theirs in finding spread of tubercle by the epithelium rare, and primary invasion by the intestinal mucous membrane common in phthisis. He observed that when the gangrene occurs in tuberculosis of the lung syphilis is a usual concomitant.

Professor Osler agreed with the previous speaker as to the lesion of tracheal and bronchial glands being a forerunner of general tuberculous pleurisy Professor Benda had shown that the simple relation of proximity to the thoracic duct accounted for this lesion being often followed by acute general tuberculosis A paper upon this subject by Dr P Haushalter and Dr A. Fruhinholz will be seen (p. 339) where they recount its occurrence in 95 per cent. of necropsies of miliary tuberculosis in children. They find the tubercle more developed and deeper seated here than in any other part, which confirms the explanation of Professor Benda. These writers deem it proof of the importance of aerial contagion in children—a conclusion formulated also by Dr G F Still two years ago upon similar evidence

Professor E. J McWeeney referred to the mode of origin of tubercle in the epididymis the question of the bacillus being sometimes incapable of demonstration from an incapacity to be stained and the fact that tubercle bacilli can circulate in the blood in considerable numbers without producing miliary tuberculosis—all problems awaiting full solution. The last, Professor Adami explained depended upon the power of the endothelial cells of the liver to destroy bacteria.

In Professor Benda s reply he said that he had never seen primary tonsillar and very rarely primary intestinal tuberculosis. He did not regard phthisis ab hæmoptoë as spreading by absorption of the bacilli from the ulcers that led to hæmorrhage, but looked upon it as simple epithelial spread by inspiratory movement. Upon the question of bacilli penetrating an intact mucous membrane he was guarded remarking how lesions of the mucous membrane may heal perfectly Tubercle of the epididymis he considered not primary but a metastasis

But few papers were read in the Section of Pathology and one only upon human histology— Excretion Tuberculosis of the Kidney From Professor Hamilton s address it would be gathered that, in the selection of his material by eliminating specimens with giant cells, Dr Hugh Walsham has probably selected cases of primary epithelial spread we cannot therefore say that his descriptions refer to the usual course of spread of disease in the kidney in cases of miliary tuberculosis.

PAPERS ON ETIOLOGY

The transactions of the Section of Medicine consist largely (one-third or more) of papers upon a variety of subjects. It is easy to say that these are of unequal value but difficult in most cases to say of what value. For many novel measures have received strong advocacy which at the Congress did not obtain full opportunity of receiving criticism accordingly it seems better to us to criticise rather than to review much of this matter

There are papers in which the dominant note is the view taken of the importance of some one factor in the etiology of phthisis.

Dr Denison brings again to our notice under the term devitalised air toxæmia" the re breathed air of MacCormac he recounted remarkable evidence in the few cases acquiring phthisis on the highlands of Colorado of their regular association with very bad ventilation

Dr Angiulli and Dr Bernheim remind us of the history of the hypophosphites. These agents had their use explained by the supposed occurrence of phosphaturia in phthisis. The same reasoning seems to be employed by Dr Angiulli in his experience of seven cases treated by phosphate of calcium ($CaH_4[PhO_4]_2H_2O$) and by Dr S Bernheim who by injecting three grammes of phosphate of creasote every other day or giving larger doses of phosphoric acid induced a hyperacid condition of the system, as does according to him the sanatorium treatment. Professor Stokvis in 1880 commenced his report upon the elimination of phosphoric acid by the urine in pulmonary phthisis by saying L'élimination de l'acide phosphorique par les urines dans la phtisie pulmonaire n a rien de caractéristique ni au point de vue du diagnostic ni à celui de la pathogenèse." The recent analyses of Goodbody and Bardswell On Metabolism in Phthisis confirm Professor Stokvis whose conclusion we may also quote Dégager la science d erreurs n est pas une œuvre stérile et dans la science comme dans le monde il vaut mieux se savoir pauvre que se croire riche."

Alteration of the respiratory exchange is claimed to be a main antecedent condition by Dr Robin and Dr Binet who for 26 years have noted increased consumption of oxygen and increased production of carbonic acid in those threatened or affected with phthisis. Of the former the descendants of consumptives they find that 13 out of 20 are thus predisposed to infection This seems too inclusive. Of the latter they find that the traditional treatment by arsenic and cod liver oil removes the abnormal condition. On the other hand Professor Cervello in setting forth the virtues of igazol (formic aldehyde, chloral hydrate terpine and iodoform combined—proportions and dose not given) sees in the increased absorption of oxygen and increased excretion of carbonic acid the best evidence of its value and this seems to be a contradictory comment upon the views of Dr Robin and Dr Binet

Dr T N Kelynack performed useful work in studying the relation of alcoholism to tuberculosis He discussed three possible views (1) alcoholism is antagonistic (2) bears no special relationship or (3) definitely predisposes to tuberculosis Valuable references were given and though unable to find substantial evidence he found much expression of alcoholic influence. Dr Kelynack might add Part II Supplement 55th Annual Report of the Registrar General p xci to his references. The inn servant with his abominable sleeping accommodation and heavy phthisis death rate, strikes us as less to the point than the slight excess above the mean to be seen in the meat-fed butcher

Dr Mignon mentioned the danger of the spread of tuberculosis in cases of insufficient nasal permeability, and recommended instruction of the public to breathe solely by the nose.

HEREDITY

Dr J E Squire informed the Congress that from 8 to 9 per cent. of tuberculous subjects inherit consumption A second series of observations expressed a similar difference between the offspring of consumptive and of non consumptive parents developing the disease

Dr Maxon King pressed the view of how great an amount of immunity is really inherited, especially when the risk of infection is also considered, and he quoted Dr Squire's figures as supporting his view In cases of phthisical parentage Dr King found the duration of the disease to be four years to three years, in these cases he did not give the ages of the groups We remember that an investigation 20 years ago found that the consumptive inheritance showed itself at an earlier age, which would not be quite compatible with increased resistance We are clearly informed that the parents may have been evidently tuberculous before or after the birth of the patient. We believe that while history shows great decline in the death rate from phthisis during the last half century it shows none in the preceding century and a half, in which case natural selection and inherited immunity must not be called upon by Dr Maxon King to explain the decline.

Dr Ernest Mosny mentioned also immunity as well as predisposition. So long is the catalogue of ills in "l'hérédo-dystrophie paratuberculeuse" that we require to feel the reassurance of actuarial calculation as given by Dr Squire. We must presume that Dr Papillon's abstract on "the hereditary arthritic forms of tuberculosis" has been badly translated, as the term "pretubercular" constantly recurs.

REGIONAL TUBERCULOSIS.

Among the most instructive papers is a series dealing with particular regions of the body We may call attention to a monograph upon Tuberculosis of the Eye by Dr Allen T Haight, supplemented by 250 references In this good work from the other side of the Atlantic we are reminded of similar work from Professor Ravenel, whose broad investigations into bovine and human bacilli supplied the Pathological Section with most timely information running somewhat counter to the surprising declarations of Professor Koch. America is further well represented in Dr H. Newton Heineman's article upon Tuberculosis of the Heart. This should be read in association with the discussion upon Professor Benda's address

Tubercle of the larynx has been minutely investigated in its association with pregnancy by Dr Kuttner His deductions are thus stated —

> 1 In women, whose recovery is hopeless, tubercular laryngitis can only be treated by the usual local remedies or by performing tracheotomy 2. In women whose general health is favourable one may so long as the affection of the larynx is insignificant (a little redness or slight ulceration) pursue an expectant plan. So soon as symptoms of infiltration show themselves or the disease extends and becomes diffuse one should acquaint the patient with the danger of her condition, and after obtaining her consent should perform tracheotomy as soon as possible and if this does not act favourably in a few days, should induce premature labour

Dr StClair Thomson described the principles of treatment, expressing clearly the difficulties of early diagnosis, also the limitations and disadvantages of one prevalent form of local treatment—the lactic acid treatment. Among his recommendations are the following —

> The most rational principle is to attempt to make an early diagnosis of the disease while in an incipient stage. Any persistent or suspicious laryngeal catarrh should be treated seriously on even a presumptive diagnosis Once diagnosed the patient should be treated on the principles laid down in the modern method of sanatorium treatment. Symptomatic treatment should be directed to any irritative catarrhal or obstructive condition of the air passages In addition, silence should be enjoined the disuse of the voice being proportionate to the degree in which the focus of infiltration approaches or interferes with the arytenoid joint

Dr Clado described a retro malleolar tuberculosis and a partial tuberculosis of the Fallopian tube.

DIAGNOSIS.

Chief in diagnostic methods stands the application of the Roentgen rays Dr Béclère describes his careful refinements of technique, Dr Hugh Walsham the advantages of the use of the photographic plate, and Dr Bonnet Leon and Dr Espina y Capo their wide experience These observers emphasise the importance of noting diminished movement of the affected side of the chest, this is sooner detected in watching the rise and fall of the diaphragm by the Roentgen rays, it would be inferred, than it is by ordinary observation Dr Leon notes that 1 or 2 per cent. of early cases may not be recognised by this method, while 5 per cent cannot otherwise be detected

In tuberculous pleurisy Dr Widal and Dr Ravant declare that a new membrane prevents endothelial desquamation and diagnosis is afforded by the absence of these cells from the fluid.

The well known work of Dr Arloing and Dr Courmont on serum diagnosis, is set forth in 20 pages of technique and results They find that 88 per cent. of those clinically phthisical give a positive reaction, Dr P Horton-Smith and Mr. H. W Armit (upon consideration of 29 cases) give the figure as 72 per cent.

Dr Lydia Rabinowitsch, with Professor Beck, found that agglutination often proved positive when there was no trace of tuberculosis and that incipient tuberculosis often gave a negative result. Even Dr Arloing and Dr Courmont found a positive reaction in 26 per cent of subjects apparently healthy, so although Professor Buard attaches a high value to it we should be afraid to let it influence greatly our clinical judgment

Mr J C R Braine-Hartnell sends from his sanatorium a scientific contribution upon rectal temperature He shows the frequent disagreement of evidence gained from thermometers in the mouth and the rectum respectively The reason for this he cannot explain, but he is convinced of the importance of rectal temperature as the more trustworthy indicator for treatment.

TREATMENT—DIETETIC

Dr Noel Bardswell's *résumé* of his work with Dr Goodbody and Mr Chapman has already been referred to It gave the proof that high feeding can become a prejudicial over feeding and supplied data of the highest value

Dr F W Forbes Ross has for a long time worked with meat-juice diet He finds ready peptonisation and prompt absorption and considers that it throws little stress upon the digestive organs, further he finds it as beneficial cooked as raw Our *confrères* from France were kind enough to provide papers with full details of their most recent researches into this diet which has been recently reintroduced there by Richet and Héricourt. Dr Josias and Dr J Ch. Roux give particulars of 16 cases Dr Cornil and Dr Chantemesse report the effect of this diet upon dogs which, it is not surprising to see, become better nourished upon a given weight of raw meat than upon the same cooked They find that besides the extra nutrition there is evidence of anti tuberculous qualities in raw meat. Dr Baradat has been employing meat-juice among his many investigations He finds, like Dr Forbes Ross, that it is as valuable cooked as raw He tells us that from one and a half to three pounds of raw meat daily are required, Dr Forbes Ross names one pound. Of the value of this diet there is no doubt, it was in use for phthisis in 1874 The results reported do not appear remarkable, but where, as is so often the case, treatment of the digestive organs is necessary, this aid may well be remembered

GENERAL TREATMENT

Papers upon treatment are remarkable for novelty, in most cases their authors in commending their treatments are unable to furnish a sufficiently long experience to impress the reader with their values. Novelty is a feature of the high frequency electrical current treatment by Dr J A. Rivière and Mr Chisholm Williams A triad of papers commend some modification of the old treatment by static electricity, whereby at the same time as the electrical discharge occurs antiseptic substances are by its aid to be transfused It is evident that besides psychical influence a great stimulating effect follows these modes of treatment, not only local but general The demonstration of the treatment of lupus by Finsen's method and by the x rays which Dr J H. Sequeira and Dr Dore gave at the Congress showed the high value of those ethereal vibrations, and it is reasonable to expect that real value underlies the high frequency current treatment, but more evidence than is given here is required before we can see what share in recovery this agency has had.

Mr A. H. Buck described seven cases of external tuberculosis which were much benefited after the administration of urea, 30 grains three times a day The analyses of urea excreted seem futile unless a constant diet is given Dr Bardswell has told us that the over fed patient may excrete 900 grains a day

Formic aldehyde is the drug most often reported upon by contributors of papers. Many are the modes of its administration—transfusion through the skin by electric current (the method of Francisque Crôtte) intravenous injection by Dr R. Maguire vaporisation at high temperatures and inhalation by Dr D J A. Chowry Muthu, and vaporisation at ordinary temperature by Dr W R. Huggard. The advantages claimed by the authors of these different methods are as yet unsupported by sufficient evidence to advocate the general use of any of them. A severe test seems to be the disappearance of bacilli from the sputum, and while this was found in 40 per cent of slight cases undergoing sanatorium treatment only in Britain Dr Maguire speaks of their disappearance in 18 out of 20 cases (90 per cent) This he considers due to germicidal action. One part in 40 000 is known to inhibit the lactic acid bacillus in milk, but not to kill it, and when we see that Dr Maguire states that the strength of the solution of formic aldehyde in the blood is 1 in 50 000 we must doubt its efficacy as a germicide until it has been shown to be more fatal to the tubercle bacillus after the further dilution which it undergoes before reaching it. We think that this disappearance of bacilli in 90 per cent. of cases is not explained Dr Huggard s paper includes the results of a wide and well analysed experience in the treatment of phthisis and will be valued by the practitioner

Mr Colin Campbell has long worked at washing out the lung by the air tubes with antiseptics. He demonstrated at the Congress his method of injecting glycerine and 3·5 cubic centimetres of izal which will render tubercle bacilli in sputum innocuous when of a strength of 1 in 125 of the mixture.

Dr F Barbary reports upon treatment by the subcutaneous injection of cacodylate of guaiacol. Dr W Ewart contributes a preliminary note upon the intravenous injection of protargol. Dr J Hobbs gave six patients persulphate of soda, one ounce a day and has commended it for treating anorexia in the tuberculous Dr Breuillard describes the effect of a combined suction, friction traction and pressure on the skin by an apparatus for pneumatic massage. Cases must be judiciously selected The effects are relief of cough, fuller respirations, and augmented appetite. Dr Breuillard claims great facility in the employment of his method by any practitioner

Many speakers and readers of papers endorsed the opinion of Professor Clifford Allbutt that sanatoriums should now carry out clinical investigation it is hard to see how otherwise an opinion can be formed of the merits of a new treatment where selection of cases will always be the main factor in results. Professor Allbutt considered that this was a duty which the sanatoriums owed to themselves lest they should sink in a slough of routine The National Society for the Prevention of Consumption and other Forms of Tuberculosis which inaugurated this successful Congress, was suggested as a possible pivot about which the sanatoriums might rotate, mutually communicating knowledge and paths of research. The society would do well to consider whether its influence for good would not be more productive in this direction than in any other

---

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8496 births and 4543 deaths were registered during the week ending Sept. 6th. The annual rate of mortality in these towns, which had been 14 4 and 15 2 per 1000 in the two preceding weeks further rose to 15 9 per 1000 last week. In London the death rate was 16 8 per 1000 while it averaged 15 5 in the 75 other large towns. The lowest death rates in these towns were 5 5 in Hornsey 5 7 in Reading 7 5 in Handsworth, 7 6 in Bournemouth, 7 7 in King s Norton 8 2 in Smethwick, 8 8 in West Hartlepool, and 8 9 in Derby the highest rates were 19 9 in Plymouth, 20 0 in Salford, 20 4 in Birkenhead, 20 6 in St. Helens, 21 2 in West Ham, 24 4 in Portsmouth and 24 9 in Burnley The 4543 deaths in these towns last week included 895 which were referred to the principal infectious diseases, against 641, 638, and 743 in the three preceding weeks of these 895 deaths 567 resulted from diarrhœa, 84 from whooping cough 83 from measles 57 from scarlet fever 50 from "fever" (principally enteric) 49 from diphtheria, and five from small pox. No death from any of these diseases was registered last week in Burton-on Trent, Handsworth Smethwick Warrington Bury or York while they caused the highest death rates in Croydon West Ham, Portsmouth Plymouth Bootle, St. Helens and Wigan The greatest proportional mortality from measles occurred in Bristol, Walsall Newcastle-on Tyne and Cardiff from scarlet fever in Wallsall and Tynemouth from diphtheria in Hanley and Burnley from whooping-cough in Portsmouth, Barrow in Furness and Hull, from fever in West Ham, and from diarrhœa in Croydon West Ham, Portsmouth Plymouth, Bootle, St. Helens Wigan, and Preston. Two fatal cases of small pox were registered in London and one each in Croydon Bolton, and Swansea but not one in any other of the 76 large towns. The number of small pox cases under treatment in the Metropolitan Asylums hospitals which had been 170 128, and 109 at the end of the three preceding weeks. further decreased to 95 at the end of last week 12 new cases were admitted during the week, against 24 18, and 11 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital which had been 2595 2623, and 2651 on the three preceding Saturdays had further risen to 2713 on Saturday Sept. 6th 333 new cases were admitted during the week, against 303, 296, and 295 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 159 130, and 139 in the three preceding weeks decreased again to 123 last week and were 16 below the corrected average number The causes of 55 or 1 2 per cent. of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol Leicester Nottingham Manchester Salford, Leeds, and in 45 other smaller towns the largest proportions of uncertified deaths were registered in Northampton Ipswich, Liverpool, Bootle and Middlesbrough

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 15 7 14 4 and 14 0 per 1000 in the three preceding weeks, further declined to 13 9 per 1000 during the week ending Sept 6th and was 2 0 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 5 3 in Leith and 10 6 in Dundee and in Greenock, to 13 5 in Aberdeen and in Paisley and 16 5 in Glasgow The 448 deaths in these towns included 31 which resulted from diarrhœa, eight from whooping-cough six from measles, six from fever two from diphtheria, and one from scarlet fever In all, 54 deaths were referred to these principal infectious diseases last week, against 64 52, and 45 in the three preceding weeks. These 54 death were equal to an annual rate of 1 7 per 1000 which was 1 4 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 23, 22, and 14 in the three preceding weeks rose again last week to 31 of which 20 occurred in Glasgow five in Dundee and four in Edinburgh. The deaths from whooping cough which had been 14 and 17 in the two preceding weeks declined again to eight last week and included four in Glasgow two in Aberdeen and two in Perth The fatal cases of measles which had been nine five and four in the three preceding weeks rose again last week to six of which two were registered in Glasgow two in Edinburgh and two in Paisley The deaths from "fever" which had been two and four in the two preceding week further increased to six last week and included four in Glasgow and two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns which had been 73, 63 and 54 in the three preceding weeks rose again last week to 61, and were slightly in excess of the number recorded in the corresponding period of last year The causes of 14 or more than 3 per cent of the deaths registered in these eight towns were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 19 5 and 20 8 per 1000 in the two preceding weeks further rose to

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING AUGUST, 1902.

* Including membranous croup

23 7 per 1000 during the week ending Sept. 6th. During the past four weeks the death rate has averaged 20 6 per 1000 the rates during the same period being 15 7 in London and 14 3 in Edinburgh The 165 deaths of persons belonging to Dublin registered during the week under notice included 28 which were referred to the principal infectious diseases, against 23 and 24 in the two preceding weeks, of these 10 resulted from measles, 10 from diarrhœa, three from scarlet fever three from " fever " and two from diphtheria, but not one from either small pox or whooping cough. These 28 deaths were equal to an annual rate of 3 9 per 1000, the death rates last week from the same diseases being 3 8 in London and 1 5 in Edinburgh. The fatal cases of measles, which had been 20 16, and 11 in the three preceding weeks, further declined last week to 10 The deaths from diarrhœa, which had been three and seven in the two preceding weeks, further rose to 10 last week. The mortality from both scarlet fever and " fever slightly exceeded that recorded in the preceding week The 165 deaths in Dublin last week included 34 of children under one year of age and 28 of persons aged upwards of 60 years the deaths of infants considerably exceeded the number in the preceding week, while those of elderly persons showed no variation. 11 inquest cases and four deaths from violence were registered, and 61, or more than one-third, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent. of the deaths registered in Dublin were not certified.

VITAL STATISTICS OF LONDON DURING AUGUST 1902.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it *appears that the number of persons reported to be suffering* from one or other of the nine diseases specified in the table was equal to an annual rate of 8 5 per 1000 of the population, estimated at 4 579,107 persons in the middle of the year. In the three preceding months the rates had been 10 3, 10 0 and 9 4 per 1000 respectively The rates were considerably below the average in Paddington, Kensington Hampstead Stoke Newington, and Woolwich while *they showed the largest excess in Fulham, St.* Pancras, Bethnal Green, Stepney and Southwark. The prevalence of small pox which had been declining during the five preceding months, showed a further marked decrease during August this disease was proportionally most prevalent in the City of London, and in Finsbury Bethnal Green Lambeth, and Battersea. The Metropolitan Asylums hospitals contained 109 small pox patients at the end of last month against 1274 837 and 305 at the end of the three preceding months the weekly admissions averaged 19, against 260 145 and 45 in the three preceding months. The prevalence of scarlet fever during the month under notice showed a slight decline from that recorded in the preceding month, among the various metropolitan boroughs this disease showed the highest proportional prevalence in Fulham, St. Pancras, Bethnal Green Southwark, Deptford, and Greenwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2222, 2439 and 2515 at the end of the three preceding months, had further risen to 2815 at the end of August the weekly admissions averaged 292, against 274 251 and 323 in the three preceding months. Diphtheria was considerably less prevalent during August than in the preceding month the greatest *proportional prevalence of this disease was recorded in the* City of London and in St. Pancras, Hackney Holborn Stepney and Bermondsey There were 1013 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 960 975 and 1003 at the end of the three preceding months the weekly admissions averaged 145 against 146 152, and 165 in the three preceding months. The prevalence of enteric *fever last month showed a marked decline from that* recorded in the preceding month among the various metropolitan boroughs this disease was proportionally most prevalent in Shoreditch Bethnal Green, Stepney Poplar Southwark, and Bermondsey The number of enteric fever patients in the Metropolitan Asylums hospitals which had been 127 195, and 239 at the end of the three preceding months had declined again to 281 at the end of August the weekly admissions averaged 38, against 19 33, and 49 in the three preceding months. The greatest proportional prevalence of erysipelas was recorded in Finsbury Shoreditch, Bethnal Green, Stepney and Southwark. The 21 cases of puerperal fever notified during the month included three in Islington, and two each in St. Pancras, Southwark, Lambeth, Wandsworth and Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the four weeks ending August 30th the deaths of 5019 persons belonging to London were registered, equal to an annual rate of 14 3 per 1000 against 15 9 13 9 and 13 8 per 1000 in the three preceding months The lowest death rates last month in the various metropolitan boroughs were 6·4 in Hampstead 10 3 in Stoke Newington 10 4 in Hackney 10 6 in Wandsworth, 11 1 in Lewisham, and 11 7 in Paddington the highest rates were 17 0 in Poplar 18 5 in Bermondsey 18 7 in Stepney 20 1 in Finsbury 20 2 in Southwark, and 21 5 in Shoreditch. The 5019 deaths from all causes included 903 which were referred to the principal infectious diseases of these 14 resulted from small pox, 108 from measles, 52 from scarlet fever 65 from diphtheria, 144 from whooping-cough, 43 from enteric fever and 477 from diarrhœa. No death from any of these diseases was recorded last month in Stoke Newington while the lowest proportional mortality from these causes occurred in the City of London Hampstead, Holborn, and Woolwich and the highest mortality in Fulham Finsbury Shoreditch Stepney and Southwark. The 14 fatal cases of small pox were seven above the average number in the corresponding periods of the 10 preceding years, three cases belonged to Islington, three to Finsbury two to Bethnal Green and two to Bermondsey The 108 deaths from measles were 36 below the corrected average number among the various metropolitan boroughs this disease was proportionally most fatal in Fulham Holborn Finsbury Shoreditch Southwark and Bermondsey The 52 fatal cases of scarlet fever showed a decline of 18 from the average number in the corresponding periods of the 10 preceding years, the greatest proportional mortality from this disease was recorded in St. Pancras, Finsbury Bethnal Green Southwark, and Battersea The 65 deaths from diphtheria were 85 below the corrected average number among the various metropolitan boroughs this disease was proportionally most fatal in Fulham St. Pancras, Bermondsey Wandsworth Greenwich and Lewisham The 144 deaths from whooping-cough showed an excess of 30 over the average number in the corresponding periods of the 10 preceding years the greatest proportional mortality from this disease occurred in Fulham St. Pancras, Finsbury Shoreditch Southwark, and Lambeth The 43 fatal cases of enteric fever almost corresponded with the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Paddington St Marylebone Hackney Lambeth, and Woolwich The 477 deaths from diarrhœa were less than one-half of the average number in the corresponding periods of the 10 preceding years; the highest death rates from this disease were recorded in Fulham, Finsbury Shoreditch Stepney and Southwark. In conclusion it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 46 per cent. *below the average.*

Infant mortality in London during August measured by the proportion of deaths of children under one year of age to registered births was equal to 147 per 1000 No death at this age was registered in the City of London Among the various metropolitan boroughs the lowest rates of infant mortality were recorded in Hammersmith, Hampstead Stoke Newington Hackney Holborn and Woolwich and the highest rates in Fulham, Finsbury, Shoreditch, Stepney Poplar and Southwark.

THE SERVICES

Royal Navy Medical Service.

Fleet Surgeon Theodore Julian Preston has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospital and Fleet

The following appointment are notified —Fleet Surgeons

J Dudley to the *Impregnable* and A. McKinley to the *Wildfire* and for service in Sheerness Dockyard Staff Surgeons J W O Underhill to the *Camperdown*, H Elliott to the *Lion*, and B C E F Gunn to the *Severn* Surgeons R. T Gilmour to the *Cæsar*, H E Fryer to R. M. Infirmary, Portsmouth, G M Eastment to the *Redbreast*, and E F Ellis to the *Gleaner*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel D L. Irvine has embarked for India. Major F S Le Quesne, V C, and Major L. R. Colledge have been posted for duty to the Western District Captain A. H Morris has been posted to the Bombay Command for duty Captain A. O B Wroughton has been instructed to join the Woolwich District for duty Lieutenant-Colonel H. H Stokes, retired, has been selected for appointment to the medical charge at Oxford, vice Major R. C Lever Lieutenant George H. Usmar resigns his commission Temporary Lieutenant M Taylor is granted the temporary rank of Captain whilst employed in South Africa.

IMPERIAL YEOMANRY (IN SOUTH AFRICA)

5th Battalion Temporary Captain P Davidson, D S O, Medical Officer, relinquishes his commission and is granted the honorary rank of Captain in the Army, with permission to wear the uniform of the corps Dated July 12th, 1901.

VOLUNTEER CORPS

Royal Garrison Artillery (*Volunteers*) 1st Banff Surgeon Captain F W Grant to be Surgeon Major

Rifle 6th Volunteer Battalion the Royal Scots (Lothian Regiment) Surgeon Captain J Cameron to be Surgeon-Major (dated Sept. 6th, 1902) 2nd Volunteer Battalion the Northumberland Fusiliers Major R S White to be Lieutenant-Colonel, and to command under paragraph 55A Volunteer Regulations (dated Sept. 6th, 1902), Frederick Newman Grinling to be Surgeon Lieutenant (dated Sept 6th, 1902) 1st Volunteer Battalion the Leicestershire Regiment Surgeon Captain W P Peake is borne as Supernumerary whilst serving with the Bearer Company of the Leicester and Lincoln Volunteer Infantry Brigade (dated Sept 6th, 1902) 3rd Volunteer Battalion the Royal Welsh Fusiliers The undermentioned Surgeon Captains to be Surgeon-Majors — R. A. Prichard (dated Sept 6th, 1902) and W J Morris (dated Sept 6th, 1902)

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY

Harwich Surgeon Lieutenant F E A. Webb, from 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment, to be Surgeon Captain Dated July 14th, 1902.

SURGEON GENERAL SIR W D WILSON, K C M G

Surgeon General Sir W D Wilson, who has arrived from South Africa, is, we understand, to take up the appointment of Principal Medical Officer in Ireland. We have more than once had occasion to refer to the valuable services which this officer has rendered throughout the long and arduous campaign in South Africa—services which have, by the way, received very scant and inadequate recognition in the official despatches published at the end of the war It is difficult to conceive a more responsible post than that which fell to the lot of Surgeon General Wilson to occupy, he was unremitting in his work and he did it most conscientiously and well and often under very trying circumstances He had earned for himself a high character as an excellent all round medical officer and very capable surgeon before he was nominated to conduct what turned out to be the biggest piece of medical administration on record as far as this country is concerned In South Africa he had to encounter and overcome great and unexpected difficulties arising out of epidemic sickness attributable to purely military causes, such as loss of big convoys, the enemy's occupation of the waterworks near Bloemfontein, the failure of transport, and other occurrences which are well known and over which he had really no control. There is one thing, however, upon which, in a self seeking and advertising age, he may fairly be congratulated—namely, on his having throughout maintained a dignified reserve and being content to go on manfully doing his duty to the end, leaving the facts and results to speak for themselves

THE ARMY MEDICAL STAFF COLLEGE.

A commencement has been made in carrying out the War Office scheme for the special training in future of candidates for the Royal Army Medical Corps in London instead of at Netley as heretofore. The recently formed Army Medical Staff College has begun its first session in the metropolis The work of the college is now being conducted at the building of the Royal College of Physicians of London and Royal College of Surgeons of England on the Thames Embankment Lieutenant-Colonel H E R. James, commandant of the depôt and training school of the Royal Army Medical Corps at Aldershot, who has been selected for commandant and director of studies in the new college, and the officers undergoing instruction, are being accommodated at the Hotel Belgravia, Victoria street, by War Office arrangement From all we hear this should prove satisfactory as a temporary measure Those quartered at the Hotel Belgravia are called upon to pay a daily contribution, fixed at a reasonable rate, out of their daily pay and allowances towards their accommodation and messing Their time will be pretty fully occupied during the day with their studies at the college, but they will have an hour's interval for luncheon and be expected to dine together in the evening at the hotel where messing has been provided for them

OUR RECRUITING DEPÔTS

Readers of THE LANCET scarcely need to be reminded that we have repeatedly called attention to the unsatisfactory position and character of the buildings usually provided as barracks for recruiting purposes Instead of being clean, commodious, cheerful, and attractive looking buildings, occupying good and prominent positions in our cities, they are commonly quite the reverse and are calculated to act rather as deterrents than as incentives to enlistment in the army We are glad to notice that this subject has recently called forth a communication from "A Recruiting Officer" to the *Times* What we should like to see, and what we feel sure it would well repay the Government in the long run to provide, would be something in the nature of a soldiers' institute—a good, cheerful-looking, well appointed building in a suitable position instead of being hidden away in some back street The building should be well lighted, of neat and cleanly appearance, and provided with good waiting rooms, offices, and lavatories, and be capable, in short, of acting as an attractive advertisement of the army as a career offering inducements worthy of attention and consideration on the part of those starting in life and seeking employment

PRESENTATION TO MR. E H. WORTH, M.R.C S ENG, L R.C P LOND, L S A.

At St Thomas's Hospital on August 20th Civil Surgeon Erskine H. Worth, on his return from South Africa, was handed an inlaid repeating travelling clock forwarded by the colonel and officers of the Sherwood Foresters (1st Derbyshire Regiment), now stationed in Pretoria. The presentation was in recognition of the unflagging energy and ability displayed by him while on medical duty with the regiment during a period of its most active service in the Transvaal. Civil Surgeon Worth was in South Africa for two years and a quarter He was attached first to the 7th Brigade Field Hospital at Ladysmith and accompanied General Buller's force as far as Lydenburg, at which place he was transferred to the Gordon Highlanders From there in turn he served at Pretoria and Johannesburgh, and was in medical charge for a time at Krugersdorp where he joined the 1st Derbyshire Regiment and accompanied them for several months in their treks under Colonel Kekewich, he having special care of the Boer women and children Finally, he saw active service in Cape Colony with the Yeomanry

A NEW PATTERN AMBULANCE WAGON

It will be remembered that as the result of experience in the late South African campaign the present pattern ambulance wagon proved to be unsuitable and a failure The topographical features of the country and the conditions under which the war had to be conducted were no doubt quite exceptional, but the present wagon has long been regarded by many people as too heavy and complicated and as being capable in some other respects also of great improvement. We learn from a Woolwich correspondent to the *Army and Navy Gazette* that in consequence of the Government having invited designs for a new army ambulance wagon of light construction several private firms and the Royal Carriage Department, Woolwich Arsenal, have entered into competition The latest arsenal ambulance as designed is larger than the wagon now in use. It weighs

32 cwt. will accommodate six wounded soldiers and is furnished with india rubber tyres and curtains.

THE SOUTH AFRICAN ARMY AND ITS CASUALTIES.

From a War Office return recently published we learn that from first to last the number of officers and men sent out to or raised in South Africa nearly reached the very large total of 450 000 The garrison in South Africa prior to the outbreak of the war numbered 12,546 and from its commencement on Oct. 11th 1899 to May 31st last there were in addition 435,889 so that a total of 448,435 altogether were engaged in the military operations Although the exact number of deaths to May 31st, 1902, is uncertain the losses in killed in action and the deaths from wounds, disease, and accidental injuries amounted to 21,942 (officers and men). Altogether 22,829 were wounded, including those who died from their wounds, and on the cessation of hostilities there were 291 officers and 9422 men in hospital in South Africa.

SOME RECENT CHICANERY IN SCIENCE

To the Editors of THE LANCET

SIRS,—I have carefully studied the paper on the Life-history of Filaria Bancrofti and Filaria Immitis by Dr L. W Sambon in your issue of August 16th, p 422, and should like to say that I for one fully concur in his criticism of the work which Professor G B. Grassi and Dr G Noè claim to have done in connexion with *filaria Bancrofti* and *filaria immitis* The experiments said by these authors to have been made by them with a view to infect dogs by the bites of mosquitoes previously infected by the latter parasite were, on their own showing badly designed and performed without due safeguards against error and were evidently rushed through and reported in haste, probably in order to forestall other observers. The observation to the effect that a number of filariated mosquitoes lost all their filariæ after a single feeding on a dog is so improbable as to suggest that it is entirely apocryphal and as Dr Sambon clearly proves, the rest of the work is equally worthless as a proof of the inoculation hypothesis of filariasis—an honour which the authors have had the assurance to claim for it.

Very little examination, however suffices to show that the work is not a serious effort of science, but only an attempt to peg out a fresh claim for priority by or on behalf of Professor Grassi. One notes at once that he adopts in his new enterprise precisely the same devices as he used previously in connexion with the mosquito theory of malaria. The moment Dr Low's work was published he hastily issued with Dr. Noè a preliminary note" in which he began by implying (but without giving details) that he himself had independently made the same discovery—a thing which I have reasons for disbelieving and then proceeded to depreciate Dr Low's work by inventing imaginary faults in it—an artifice which he consistently adopts in regard to my own work. Having thus shifted the merit of the inoculation hypothesis of filariasis to his own credit, he permits his pupil, Dr Noè, to draft the entire subject into his account by saying that the Italian discovery now at last enables us to place the prophylaxis of filariasis upon a solid basis " Needless to say neither he nor his pupil has ever made a single new observation on filariasis while, even as regards *filaria immitis* of dogs, the mode of propagation was discovered, not by them, but by Calandruccio guided by Manson's previous work. And now when the actual experiments which we were told would support this extravagant claim are published they turn out to be worth nothing at all.

I have long had a very familiar acquaintance with a certain order of Italian literature on cognate subjects and may take the present opportunity to warn others against accepting too readily as some appear to do the claims of priority or even many of the observations contained therein. Whenever a new discovery is announced the authors of these works are pretty sure to attempt to obtain the principal credit of it by publishing hasty preliminary notes" suggesting that they had already made it, followed by endless monographs disparaging their predecessors, distorting the whole history of the discovery and recording observations which turn out to be for the most part either easy confirmatory work or else entirely wrong Take for instance the whole history of our knowledge of malaria—the invention of the bacillus malariæ by Crudeli and Klebs the efforts of Marchiafava, Celli and Bignami upon Laveran's discovery (so well exposed by him in his Traité du Paludisme, ' p. 42) the *amœba guttula* of Grassi and his colleagues, the 'proof" of the mosquito theory of malaria by Bignami, and the discovery' of the '*anopheles malariferi*" by the epidemiological studies of Grassi to name only a few and by no means the worst examples. The very peculiar methods adopted by Grassi, especially for securing scientific distinction for himself have already been publicly commented upon by Parona[1] Calandruccio,[2] and myself,[3] and are now ably scrutinised by Dr Sambon. The skill, subtlety, and audacity of the chicanery employed in the efforts referred to deceive easily the cursory reader but really the more careful student is beginning to be somewhat sceptical when he sees the announcement of a new 'Italian discovery I refer of course, only to this particular school of Italian writers.

It is a question how to deal with such efforts In my humble opinion science is too great a thing to be made a field for tricks like those of a pettifogging village attorney and we have every right to resent their introduction. Moreover absolute honesty is the first qualification in all scientific work and the man who attempts to deceive his readers on questions of priority can hardly complain if we refuse to believe in his researches—a person who will deceive in one respect will deceive in another Others may do as they please, but for my own part (as I have already publicly stated) I fear I cannot do myself the honour of including the labours of Professor G B Grassi in any future writings of my own and I think that science will not lose much if the papers by him and Dr. Noè on filariasis are similarly excluded from monographs on that subject.

I am, Sirs yours faithfully

Sept. 6th RONALD ROSS.

PS.—Two other instances of the same kind have just been brought to my notice. Early last year Nuttall published a note announcing the important observation that *anopheles* can exist where there is no malaria. Some time later Celli published similar observations but stated that Nuttall's work confirmed his—implying quite erroneously that Nuttall's observations were secondary to his Again in 1899 Grassi[4] published a note stating that he had found *piroplasma bigeminum* a parasite of cattle previously known to be inoculated by the bites of ticks in the salivary glands of those arthropods, and promising to publish the full account of the discovery later Needless to say the full account has never appeared. It will be interesting to note what happens when someone really does make the discovery

INSANITY AND LONG SEA VOYAGES

To the Editors of THE LANCET

SIRS,—At a period of the year when people in delicate health are already making their plans to escape from the drawbacks of an English winter and medical men are constantly being consulted as to the advisability of this or that course, a note of warning in respect to some cases may not be out of place. It is especially to those cases which exhibit a tendency to melancholia that I wish to refer—those who from worry bereavement or overwork, have become chronically run down and who at last seek in change and travel the necessary stimulus to enable them to weather the storm With such change is often beneficial but long sea voyages are quite a different matter To allow such patients to undertake unattended as is too often done long runs even on fast liners is a grave mistake. It is thought that the pleasant companionships and the *facilities for social intercourse* which are the most charming characteristics of life on board these floating hotels, combined with the exhilarating influence of the sea air and the uneventful restfulness of long days free from even an echo of the world's turmoil, cannot but prove beneficial to those whose nervous systems have been overwrought. All this is excellent in theory, but in practice it leads to anything but satisfactory results It is quite true that there are plenty of opportunities for pleasant companionship and amusements of all kinds, but only for those who care to seek them, there are few places where a man can isolate himself from his fellow creatures and be alone in a crowd so easily as on board ship And this is exactly what happens with a person suffering from mental depression or from *ennui*, he does not seek to mix with his fellow passengers, he has no inclination to do so and consequently he is ignored by them, he sits for hours together in his deck chair, incapable of concentrating his thoughts on a book, and simply brooding over his worries, supposed or real He has no opportunities for exercise, the decks are generally too crowded with chairs for that, he has not the ordinary little incidents of every day life on shore to rouse him, he has no theatres to go to where he can be amused without any effort on his own part, in a word, he cannot get away from himself Under these conditions it is easy to see how what was merely a tendency before will rapidly become confirmed melancholia He has nothing to look at but the eternal ring of blue sea of which the ship is the centre, he has no ears but for the noise of the swirl of the water against the ship's side, which to him soon becomes irritating, and the regular throb of the engines only beats a tune to his depressing thoughts What should be repose and quietude becomes an endless monotony, if he seeks refuge in sleep during the day his nights will in consequence be sleepless and after a week or 10 days of such a life his condition will be worse than when he started

[3] Ross: La Scoperte del Professor G B Grassi sulla Malaria—Il Policlinico 1900 and 1901

[4] *Grassi*; Rendiconti della R Accademia dei Lincei 1899

But there is another factor which must not be lost sight of in connexion with these cases and that is the over stimulating effect of the saline breezes whose influence for good is so confidently looked forward to Their action, however, is purely physical and this constant physical stimulation coinciding with constant and increasing mental depression is apt to bring on, if the voyage is protracted, paroxysms of acute mania, and it is not infrequent to find on board ship among these patients very typical examples of what the French call *la folie à double forme*

In long voyages on sailing ships these dangers are increased tenfold and on no account should such patients be allowed to contemplate such a step The therapeutical value of sea voyages in many classes of diseases cannot be overrated, but where there is the least sign of incipient insanity in any of its forms or merely a condition with a remote possibility of such a contingency they should be most strongly deprecated. In any case the patient should never be allowed to travel alone or merely with an attendant of whom he cannot make a social companion, he should be with a friend or a member of his family and best of all with a party It should always be borne in mind that the ocean, with all its fascination, with all its healthful properties, has an element of world weariness about it which even hardened sailors experience and from which they only escape by the multifarious duties of their calling I am, Sirs, yours faithfully,

Sept 5th 1902 LOUIS VINTRAS, M.D Durh, B Sc Paris

INTESTINAL SAND

To the Editors of THE LANCET

SIRS,—With reference to Dr A Crombie's letter[1] commenting on that part of my note on "True" Intestinal Sand,[2] which related to his remarks during the discussion on the paper read by Sir Dyce Duckworth and Dr A. E Garrod at the Royal Medical and Chirurgical Society in 1901, I wish, in the first place, to thank Dr Crombie for dispelling the doubt I had as to the nature of his cases In his remarks on the above-quoted occasion he made no reference to the very important fact that the specimens had been subjected to a chemico-microscopical examination, and in the absence of such a statement I naturally concluded that the specimens had not been so examined

Might I suggest to Dr Crombie that he should publish an account of his cases? These cases of intestinal sand appear to be of such rarity that any contribution to our knowledge of the condition—especially when clinical facts can be supplemented by the results of analysis—cannot fail to be of much interest I note that Dr Crombie has quite recently had a case of pernicious anæmia in which small quantities of intestinal sand were detected It is to be hoped that in this case a complete analysis of the sand was made I infer that this was done, as Dr Crombie describes it as a case of "true" sand, and, of course, the differentiation from the false variety can only be made by analysis and microscopical examination

May I venture one comment on the case referred to in the last two sentences of Dr Crombie's letter? The patient therein referred to had, previously to consulting Dr Crombie, been "living an ordinary life on mixed diet," and Dr Crombie noted that no tinned Californian fruits had been eaten for the previous three months Mixed diet would in Calcutta include, in all probability, fresh plantains or bananas and might include figs It is well recognised now that these fruits may give rise to "false" intestinal sand as well as the pears which Dr Crombie excludes from the possibilities of his patient's dietary

In conclusion, it may be of interest to state that since the publication of my note on this subject I have been afforded, through the kindness of Major D M. Moir, I M.S, an opportunity of examining a specimen of intestinal sand which he received in 1892 from Dr Birch, then principal of the Calcutta Medical College I could not obtain any clinical facts in connexion with the specimen There were unfortunately only remaining a few grains of this specimen and so it was impossible to make a full quantitative analysis The results obtained were as follows moisture, 3 94 per cent, inorganic matter, 7 62, and organic matter, 88 44 The microscopical appearances were very similar to those obtained in the specimen of "true" sand already described by me In this case the percentage of *inorganic* matter (7 62) accords more nearly with the amount which has been previously found in specimens of "false" sand (generally from 2 to 3 per cent), but the microscopic appearances and the results of treatment with various reagents while the specimen was under the microscope correspond with those obtained in the case of "true" sand I am inclined, therefore, to regard this specimen as one of "true" sand with an unusually small proportion of inorganic constituents I am, Sirs, yours faithfully,

C H BEDFORD, D Sc M D Edin,
Major I M S Chemical Examiner to the Government of Bengal
Calcutta Medical College, August 19th, 1902

P S —In my paper above referred to the date of Professor Delépine's paper was misprinted 1900 It ought to have been 1890

THE LOW PHOSPHATES AND UREA IN THE URINE OF THE TUBERCULOUS

To the Editors of THE LANCET

SIRS,—In your issue of Sept 6th, p 656, I read with much interest Mr E G Clayton's valuable contribution on Some Observed Variations in the Phosphates and Urea of Urine Mr Clayton says "The unusually low phosphates and urea in the case of tuberculosis and in sample B, as well as the evident general correspondence of the preparations of both constituents in the varying conditions represented seem to be the points most worthy of remark." The analysis of urine in the case of tuberculosis of the bladder confirms my argument as to the value of pure urea in the treatment of tuberculosis In my papers on urea published in THE LANCET of March 9th (p 694) June 15th (p 1672), and Dec 7th (p 1567), 1901, I stated that the tuberculous are deficient in nitrogen and that urea given with abundance of animal food supplies this deficiency and is the best remedy that at present we possess. Further, "that tuberculosis bears an inverse ratio to the amount of proteid consumed—that is to say, the less animal food ingested the greater the number of tuberculoses, and *vice versâ*" "For years I have been struck with the low specific gravity and deficiency of solids in the urine of this class of patients"

I am, Sirs, yours faithfully,

Nottingham, Sept 8th 1902 H HARPER, M D R.U I.

WOMEN INSPECTORS OF THE LOCAL GOVERNMENT BOARD

To the Editors of THE LANCET

SIRS,—I am afraid that your Welsh correspondent has not devoted much study to the question of boarding out pauper children or he would be aware that there are *three* inspectors of boarding-out. These ladies were appointed to see that the committees did their work well, and if your correspondent will go through the reports of Miss Mason he will find that certain of the committees did it very badly—so badly that in some cases the Local Government Board refused to allow them to take any more children and in at least one case cancelled the order It is the committees that Miss Mason and her colleagues inspect and to gain that knowledge of the way they do it they have to visit a considerable number of the children boarded out *beyond the union*." The inspectors have nothing to do with children boarded out *within the union*, and when I state that while the children boarded out beyond the union number less than 1900 those boarded out within the union number upwards of 5600 it will be at once seen that *less* than a third of the children are even liable to be inspected by the officials of the Local Government Board. I am no advocate of women indecently usurping men s place in public administration, but I do think that girls boarded out, either singly or with societies or sisterhoods, should be inspected by women if only to prevent the recurrence of a scandal similar to the one that has just occurred in Lancashire.

HAS ACUTE ANTERIOR POLIOMYELITIS BEEN UNUSUALLY PREVALENT DURING THIS SUMMER?

To the Editors of THE LANCET

SIRS —I see a letter in THE LANCET of Sept. 6th p 707 from Dr F E. Batten stating that in his experience acute anterior poliomyelitis has been unusually prevalent during the present summer In answer to his query I may say that I have been struck with the number of cases of this disease which I have met with during the past few weeks and I was therefore very interested to read the letter above referred to

I am, Sirs, yours faithfully
Cardiff Sept. 8th 1902. W MITCHELL STEVENS.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

Another Threatened Plague Outbreak.—The Death rate in Madras City —Infant Mortality in Bombay and Calcutta

THE mortality from plague throughout India has been steadily rising during the past few weeks For the week ending August 9th the deaths were 2854 while for the past week (ending the 16th) they have risen in number to 3762. The rise has not been limited to one province but is almost general. The figures for the week are Bombay Presidency 2642, as against 2225 for the previous week Madras Presidency 145 as against 144 United Provinces 153, as against 29, Punjab 106, as against 23 Mysore 612, as against 392 Berar 34 as against 18 The only province which shows a decline is Bengal where there were only 10 deaths and in the city of Calcutta only nine deaths. Plague is gradually creeping nearer Simla Kasauli having had already 11 deaths. These increasing deaths taken in conjunction with a rise at the corresponding period last year are a sufficient indication of what we may expect, and now that the disease has extended to so many provinces its ravages are likely to be enormous Moreover it shows that the great Punjab inoculation scheme has hardly been taken in hand sufficiently early The medical officers are not all distributed—in fact, they have not all arrived in India—and the organisation of the work is far from complete. This inoculation scheme should give an opportunity for testing other fluids than that of Haffkine. While the advantages of this serum are unquestionable it is admittedly open to improvement and it possesses certain drawbacks The serum of the Berne Institute may be mentioned as deserving further trial as a curative agent

I have had from time to time to draw attention to the high death rate in Madras city During the past year it has been 55 5 per mille as against a mean of the previous five years of 40 9 It is said that the climatic conditions were unfavourable but the water supply was imperfect and the drainage defective and inadequate. What Madras wants is a bold scheme of improvement for opening up the congested portions of the city similar to the work now being carried out in Bombay The municipal finances are such that any great scheme cannot be entered upon without Government assistance and already they are under the burden of 30 lakhs for drainage. A better system for the registration of the causes of death is urgently called for Improvements in this direction have been made both in Bombay and in Calcutta. I hear that in Calcutta every death is inquired into and that from the history of the illness the district health officer is able to form an estimate of the probable cause of death Though admittedly imperfect this is vastly superior to dependence upon the mere statements registered at the burning ghauts or burial-grounds by the deceased s relatives Failing the certificate of a medical practitioner this seems the only possible means of obtaining anything like a probable estimate of the cause of death I doubt if anything so thorough as this is done anywhere else in India.

The 37 medical men who are coming out to India for plague work in the Punjab will be inoculated shortly after arrival in Bombay and they will be detained for a short instruction at the Research Laboratory before being sent forward for duty

The infant mortality in Bombay is apparently enormous For last year the rate of male infant mortality was 571 in 1000 of the births, and the female ratio was 589 The Government declines to accept the theory that the registration of births is defective. Very much the same high mortality prevails in Calcutta where the deaths of infants under one month have been found to be excessive But for this city the health officer considers the low birth rate recorded as due largely to deficient registration. The deaths of infants under one year were at the rate of 408 5 per 1000 births but the birth rate is only about 10 7 per 1000 of the population

August 23rd.

HOSPITAL ABUSE

(FROM OUR SPECIAL COMMISSIONER.)

The Leigh Medical Society and the Proposed New Hospital — United Action of the Medical Profession to Prevent the Creation of Conditions that lead to Abuse

THE proposal to build a hospital at Leigh was brought before the Ethical Section at the recent annual meeting of the British Medical Association The remarks made by Dr F E. Wynne a local practitioner were published at the time. He pointed out that there was no need for an outdoor patient department that it would compete unfairly with the practitioners of the district, and that its creation had been proposed so as to obtain subscriptions from the working class. The medical men concerned had protested but had been treated with scant courtesy and they had been threatened with the importation of an outside surgeon who would be encouraged to practise in opposition to them. It seemed to me a rather serious matter if a scheme for a hospital should even at its inception thus assume a hostile attitude towards the profession. Consequently I went to Leigh to inquire on the spot and to obtain fuller details Here I found that what is called Leigh is really an amalgamation of three districts, West Leigh Pennington and Bedford which together have according to the census of 1901 a population of 40 001 inhabitants It is a colliery and manufacturing district six miles from Wigan seven miles from Bolton, and 12 miles from Manchester But within two miles there is the district of Atherton with 16,211 inhabitants and at a distance of two and a half miles there is the town of Tyldesley with 15 000 inhabitants Adding these two figures to the population of Leigh we have some 71 000 persons for whom there is no hospital Apart from the ordinary cases that require hospital treatment severe colliery accidents occasionally occur and it is certainly a hardship to have to convey such patients all the way to Wigan or to Manchester for hospital treatment. The population of these places is growing Leigh is a convenient centre and if a hospital were built in this town it would certainly render considerable and welcome service Therefore when rather more than a year ago a movement was set on foot having for its purpose the building of a hospital it was widely approved by the members of the medical profession as well as by the other sections of the community A town s meeting was convoked which elected a large committee to promote the project. The mayor, members of the town council, all the clergy, and the medical men were appointed members of this committee.

It was not till this general committee had met a few times that differences began to arise. The general committee appointed an executive and only one medical man was selected to serve on this body. The executive proceeded to invite architects to submit plans for the proposed hospital and these were to comprise an out-patient department with a waiting-room large enough to hold more than 100 persons. Thereupon the Medical Society of Leigh made a formal protest and appointed a deputation to wait upon the hospital committee. The members of this deputation do not consider that they were well met; in fact, it seems as if they were treated rather rudely. In any case, the medical practitioners of Leigh were so far offended that they determined that they would have nothing more to do with the matter unless they were specifically invited to help. But now that some time has elapsed since these regrettable incidents occurred the matter is viewed in a calmer light and it is acknowledged that the medical men have been somewhat remiss in educating those with whom they had to deal. What is obvious to a medical practitioner is not necessarily understood by those who are outside the profession. Now that there has been time for explanations and friendly discussion the standpoint of the profession is much better understood, notably by the mayor, the secretary of the local coöperative society, who is a town councillor, and others. Undoubtedly, the Medical Society of Leigh ought from the very onset to have laid their case before the general public. Many misunderstandings would thus have been prevented and the members of the profession would not have been subjected to unjust aspersions. There are 15 or 16 local practitioners and, with one exception, they all belong to the Medical Society which was founded four years ago as a medical guild or union organised to deal with economic questions. The one exception will work with the Medical Society in regard to the hospital question and therefore it may be said that the local practitioners are unanimous. They do not object to the creation of a hospital but they maintain that an out-door patient department is not needed and would be very injurious to the profession. There is, for instance, a colliery in the neighbourhood where as many as 3000 men are employed. From time to time serious accidents occur in the pits and it is in view of such catastrophes that there is need for a hospital. But there are also ironworks, manufactories of agricultural implements, and some small industries. Here minor accidents occur consisting generally of injuries to the hand or the eye. The patients in such cases can easily walk to a practitioner's private surgery; no hospital is required for such slight accidents. The employers at these various firms sometimes pay a regular sum to local practitioners to attend any of their workmen who may be injured. Some of these practitioners receive £20 a year from several firms and would not be able to live if these payments were withdrawn. But if there were a hospital with an out-patient department these employers would probably subscribe to the hospital instead of paying a local practitioner, and would send their workmen to the out-patient department where they would be treated for nothing. Indeed, the employers could save money in this way while figuring as patrons of the local charity. On the other hand, the money which now enables several practitioners to make both ends meet would be swallowed up by the hospital.

In large centres where there is a great mass of poverty it may be necessary to have out-patient departments at some of the hospitals. At Leigh there is comparatively little poverty. There is little or no casual labour. The inhabitants for the most part are in regular employment. Drunkards and men with very large families may find it difficult to pay their way; but, as usual, the medical practitioners are constantly attending gratuitously on such cases. Therefore they maintain that there is absolutely no need for an out-patient department and this assertion is confirmed by the fact that there is as yet no medical charity whatsoever at Leigh. If the necessity for a medical charity has not yet been felt, why should such an institution be forced on to the community merely because there is need for surgical wards to meet emergencies when serious accidents occur? A serious case requiring indoor hospital treatment is a very different matter. Nevertheless, the plan for the hospital which has been adopted includes a large out-patient department. The only concession which as yet has been made to the medical profession is the abandonment of a proposal that the paid house surgeon of the hospital should visit patients in their homes. This, in any case, has been recognised as unfair competition, so that some advantage has already resulted from the united action of the members of the profession. The local practitioners are inclined to boycott the hospital unless the managers consent to limit very strictly the out patient department. It is true that as yet the exact meaning of the word "limit" has not been defined, but it is felt strongly that for small accidents and ordinary illnesses the great mass of the population can afford to pay at least minimum fees. On the other hand, where well-established cases occur for which such payments cannot be made the local practitioners are willing to treat such cases at their own surgeries gratuitously. Why, then should there be an out-patient department, where it will be almost impossible to prevent abuse, when the local practitioners are willing to attend necessitous cases gratuitously? Why increase the cost of building the hospital by adding an out-patient department and then augment its working expenses when all that is really needed will be supplied from the private surgeries of the local practitioners without involving the subscribing public in any cost whatsoever? But there are working men colliers on the hospital committee and they insist on the creation of an out patient department. On the other hand, would they so insist if they did not anticipate that such a department would be the means of obtaining for many cheaper medical attendance? It is this tendency which the local practitioners are in self defence bound to resist. Where charity is needed they will give it; where the patient can afford to pay they demand such payment. But the aim is to avoid full payment by means of penny subscriptions and, on the other hand, to disguise charity under the cover of these small donations. If the members of the profession hold out it is difficult to see how the hospital can be managed. A junior paid house surgeon cannot do all the work. A visiting staff selected from among the local practitioners must be formed but this will not be possible if these all refuse to serve.

One cause of the present difficulty is the precedent established by the hospitals of Wigan and Bolton. In both these towns there are out-patient departments to the hospitals and the workmen there are in the habit of subscribing to these hospitals, so the workmen of the Leigh district naturally imagined that they would be able to do the same in regard to the new hospital which it is proposed to build. But at Wigan and Bolton there are endowments and old-established charities which tie the hands of the managers. Nothing of the sort exists at Leigh. From the Wigan hospital eight tickets of recommendation are obtained for a guinea subscription and this is a proceeding that lends itself to much abuse. Reform is greatly needed in regard to this matter at Wigan. At Oldham only two tickets are given in exchange for a guinea subscription entitling the patient to one month's treatment. What has proved to be a cause of much abuse in the two nearest towns should serve as a warning rather than as a precedent to be followed.

After talking these matters over with several local practitioners I called on the secretary of the hospital committee to see what might be said on the other side. But the secretary energetically protested that he did not belong to any side and was earnestly endeavouring to be absolutely impartial. He thought that every practitioner in Leigh had a large free list and that it would be to their advantage if these non paying patients were transferred to the out-patient department of the hospital. All new comers to the district were besieged by these bad paying patients. Nor would it be altogether wise to send those who really could not pay to the Poor-law medical officer. The class that went to the parish medical officer would soon conceive that as they got medicine for nothing they might as well endeavour to get milk for nothing, and finally they would come down on the parish for permanent relief. The hospital outdoor patient department would draw off this class and would help to prevent pauperisation. But if such results were likely to be beneficent there certainly was a great danger of abuse. To prevent this it would be necessary to draw up very stringent rules and the secretary also thought a medical receiving committee should be formed so as to see that only worthy subjects for charity were admitted. The hospital, it was estimated, would cost about £13 000 and £9000 had already been promised. The land had been given to them by Lord Lilford and therefore there is every hope that the scheme will be carried out. They might get the foundations out this year and commence building next year There will be a pavilion of two storeys, with a ward for 15 beds on each floor The one will be the female the other the male, ward. Then there are the administrative buildings and the out-patient department, but the plan is so contrived that this latter could be left out altogether There is space remaining on the land for the building of more wards should the necessity arise, which judging from the present rate of increase in the population, is likely to be the case at a future date. It seems certain that the project to build a hospital will be realised, so that here there is a test case. There is, on the one hand the well established fact that hospital abuse exists on a large scale throughout the country On the other hand a certain number of medical unions have been formed to deal with this and other economic questions. The Medical Society of Leigh is especially favoured in having secured the unanimous support of all the local practitioners There could be therefore no better opportunity for the practical demonstration of the utility of such a medical union. It is to be hoped that the medical practitioners of Leigh will rise to the occasion and set an example that will be useful throughout the United Kingdom. They are not hampered by vested rights and established precedents. In respect to the question of hospital abuse they are treading on virgin soil and should therefore be able to establish a new precedent, to enforce the application of new principle and to realise much needed reforms

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Congress of the Sanitary Institute

THE arrangements made for the annual congress of the Sanitary Institute allow of the confident expectation that the meetings which are to begin to-day (Tuesday Sept. 9th) should be very successful. The Lord Mayor will welcome the members at the town hall after which he will preside at a public luncheon, and at 3 o clock he will open the Health Exhibition at St. James s Hall. At 8 o clock in the evening Earl Egerton of Tatton the President of the congress will give the inaugural address at Owens College. The active business is to begin to-morrow the 10th. Conferences will be held respectively by municipal representatives port sanitary authorities, medical officers of health, engineers and surveyors to county and other sanitary authorities, veterinary inspectors, and sanitary inspectors, and on the hygiene of school life. To-morrow afternoon there is to be a garden party at Tatton Park on the invitation of Earl Egerton of Tatton and the Duchess of Buckingham and Chandos and in the evening the lecture to the congress will be given by Dr W N Shaw his subject being The Treatment of Smoke a Sanitary Parallel. On the 11th there are to be meetings of sections—No. 1, which deals with Sanitary Science and Preventive Medicine, under the presidency of Sir J Crichton Browne No. 2, for subjects relating to Engineering and Architecture with Sir Alexander Binnie in the chair and No. 3, dealing with Physics Chemistry and Biology presided over by Professor Delépine. The meetings of the sections will be continued on the 12th and in the evening of that day Sir W J Collins will give a popular lecture on The Man *versus* the Germ Many visits and excursions have been arranged for the various clubs are throwing open their doors to members, and much hospitality will be shown Good no doubt, will be done by the gathering and the attention of a portion of the intelligent public may be drawn to some of the sanitary evils which still oppress us, but will it end chiefly in talk and not be followed by action? Will the lecture on the treatment of smoke be followed by its diminution to any appreciable extent? So long as so many evil deeds—from the point of view of sanitation—are winked at, if not expressly permitted they will be continued whilst it pays to do so by a large proportion of the offenders But the time has surely come when more stringent measures might be used without injury to the manufacturing interests. The appliances for smoke consumption have been greatly improved and have been found to save fuel and money but there still seems to be some prejudice against their use. Much, also may be gained by the more general use of gas-engines and of electric appliances. As regards personal and domestic hygiene one difficulty is to educate the most ignorant of the population, and perhaps some suggestions may be thrown out at the congress which will bear fruit

Lunatics in Workhouses.

An inquest was held about a fortnight ago on the body of a man who jumped through a window in the workhouse infirmary at Crumpsall. He was taken in custody for behaving in an extraordinary manner" at the Victoria Station brought before the magistrates, acquitted of the charge of trespass, and ordered to the workhouse, but owing to some misunderstanding he was not put into the lunacy ward. The master of the workhouse stated that the medical officer did not think the man insane, but if he had done he would have had him transferred to the imbecile ward and he would have had him brought before the magistrates within 36 hours. In reply to the coroner the master also said that if he had received an order from the magistrates he would have put the man in the imbecile ward despite the medical officer's opinion. It was further stated that no written order was given by the magistrates and the only one received was from the relieving officer stating that the man appeared to be subject to delusions The case was adjourned for the evidence of the medical officer

Boys Camp at Southport

There is one manifestation of modern philanthropy which seems altogether good—namely that of taking poor children for a week or two in summer to the seaside or into the country Over 2000 city lads have lived in camp at Birkdale Southport since the season began in Whitsun week They are from the very poorest class and but for the Strangeways Refuge would have had no change from the courts and alleys in which they live. The camp is close to the sea. Most of the boys sleep in army tents, which are kept perfectly sweet and clean but a large wooden dormitory has been recently added. Workers among the poor report to the managers of the Refuge cases likely to be benefited by a week in camp. The candidates are medically examined before going Each working boy pays 2s. towards the week's expenses and each schoolboy 1s but in cases of extreme poverty this is not insisted on. The total cost of each lad s journey there and back and his stay in camp is 6s On reaching camp his clothes, often merely dirty rags, are changed for a strong suit provided by the managers The change from the confined slum to the spaciousness of the open beach is a revelation to most of the lads that carries with it something of pathos. One little fellow said I've never seen so much room out of doors before. And another looking at the sea for the first time said What a big cut," which is vernacular for canal his notion of water on a large scale being derived only from the canals of the city or perhaps from the Medlock and the Irwell They bathe every fine morning are drilled each day play to their hearts content, and are abundantly fed so that the pale, pinched looking undersized city children, telling of rapid and serious degeneration of race, go back wonderfully invigorated and browned The pity is that the stay is so short and that the return in most cases is to a closed insanitary slum At the end of the season the committee find themselves £75 in debt, but it is hoped that this will soon be cleared off and that a start will be made next year free from this burden.

Sept. 9th

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Winter Session of the Medical Faculty of University College, Liverpool by Sir Frederick Treves Bart K.C V O C B

THE inauguration of the winter session is looked forward to by the students of the Medical Faculty of University College, Liverpool, with the greatest interest as the occasion will be a memorable one in the annals of the Liverpool school. Sir Frederick Treves has kindly accepted the invitation of the Medical Faculty of the College to distribute the prizes to the successful students and to deliver the opening address on Friday Oct. 10th at 2 P.M. It has been arranged that the professorial staff and the former students of the college, wearing academic costume shall walk in procession from the college in Brownlow hill to the Philharmonic Hall where the ceremonies will take place. The hall is a spacious one and is capable of accommodating some 3000 persons. Special efforts have been made by the dean of the medical faculty to trace former students, many of whom have already received invitations to attend the ceremony If those who have not received invitations will convey to Dr T R. Bradshaw, 51, Rodney street, Liverpool, their desire to be present invitations will be forwarded to them The orchestra will be reserved for past and present studies Upon the termination of the proceedings at the Philharmonic Hall a procession on similar lines to the former one will be made to the Royal Infirmary, where Sir Frederick Treves will open the new operating theatres Tea will afterwards be provided in the corridors by Mr Edward Kewley, the genial chairman of the committee. The two new operating theatres at the Royal Infirmary have been erected through the generosity of an old and valued member of the committee and are equipped with all the most recent requirements of modern surgery The biennial dinner of the medical faculty of University College will take place in the evening of the same date at the Adelphi Hotel. Sir Frederick Treves will be present, together with other distinguished guests

Sept. 9th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

The Census Returns for Glamorganshire

THE complete census returns, which have just been issued for the county of Glamorgan, give some very interesting figures with regard to the amount of overcrowding in the county and by a comparison with the returns for 1891 it is possible to ascertain to what extent the conditions found in 1901 differ from those existing 10 years earlier In the census report for 1891 it is proposed that tenements should be considered overcrowded when occupied by more than two persons to each room, and applying this standard among the tenements of less than five rooms in the whole county 8 per cent were overcrowded in 1901, while in 1891 the percentage was 12 In the county borough of Cardiff the overcrowding was reduced from 9 per cent in 1891 to 6 per cent in 1901 and in Swansea during the same period the reduction was from 12 per cent to 8 per cent In the urban districts of the county 9 per cent and in the rural districts 6 per cent of the tenements indicated were overcrowded in 1901 Except in Merthyr there is shown to be a marked decrease in the large urban districts during the 10 year period In Aberdare the percentage fell from 10 to seven, in Mountain Ash from 12 to eight, in Neath from 12 to 10, in Ogmore from 22 to 10, in Pontypridd from 14 to seven, and in the Rhondda valleys from 20 to 11 It would appear, therefore, that in all these towns the additional housing accommodation provided has much more than kept pace with the increase in population In Merthyr, on the other hand, in 1891 there was overcrowding in 15 per cent. of the tenements with four rooms or less and the same percentage prevailed in 1901 There is thus ample justification for the action of the Merthyr district council in erecting 100 workmen's houses which are now in course of being built and which will go far to lessen the overcrowding of cottages undoubtedly existing in the town In the rural districts, some of which, however, are rural only in name, the amount of overcrowding is not so great as it is in the colliery districts, though in only two—Gower and Llandaff—is the percentage less than that found in Cardiff, while in Neath rural district 10 per cent. of the small tenements are overcrowded, and in Cowbridge and Gelligaer rural districts the percentage is eight In 1901 there were 103,358 men and boys working in the Glamorganshire collieries, a number about equal to 30 per cent of the male population above 10 years of age, an increase of 3 per cent upon that recorded in 1891 In the Rhondda valleys and in Merthyr this percentage was 48 and 42 respectively Among the total number of colliers employed in the whole county only 1572, or about 1½ per cent were above 65 years of age, and it is of interest to record that in 1901 there were only 84 women stated to be working about the collieries, and these all above ground, while in 1891 there were 299, and in 1881 there were 429 so employed.

Madame Patti at Brecon.

Madame Adelina Patti (Baroness Cederström) gave a concert on Sept. 3rd on behalf of the Brecon County and Borough Infirmary The large covered market hall of the county town, holding about 2000 persons, was quite filled and Madame Patti was most generous with her encores to each of her four songs The members of the concert party, which included Mr Santley and Mr Wilhelm Ganz all gave their services, but all the other expenses were borne by Madame Patti, so that the infirmary, which was established in 1833 and contains 16 beds, will receive a welcome and substantial addition to its funds

Memorial to a Newport Medical Practitioner

It has been decided to erect a drinking fountain in Beechwood Park, Newport, Mon., in memory of Dr John F L Mullin who died in February last after practising in the town for over 10 years The cost of the memorial is being defrayed by a shilling subscription to which the working people of the town have largely contributed

Vaccination Questions

At the meeting of the St. Thomas (Exeter) board of guardians held on Sept 5th a letter was received from the Local Government Board stating that a vaccination officer could take proceedings without the direction of the guardians, whilst the giving of a notice before a visit of the public vaccinator was not necessary to a conviction. The vaccination committee, who had been considering the question of the vaccination fees, recommended that it was desirable to give a month's notice to terminate the contract to the public vaccinators for St. Thomas and Starcross respectively, and the guardians decided to take that course.—At the meeting of the Barnstaple board of guardians held on August 29th it was reported that 474 births were registered in the union during the six months ended December, 1901, and that during the same period 365 children were successfully vaccinated and 29 received certificates of exemption

Exmouth Cottage Hospital

The foundation stone of the Exmouth Cottage Hospital was laid on Sept. 3rd by Lady Gertrude Rolle The building will contain on the ground floor two main wards, measuring 30 feet by 20 feet, and providing accommodation for six patients each, in addition to which there will be special wards, a surgery, &c The estimated cost is about £4000, of which £3000 have already been raised.

Sept 8th

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Sanitary Association of Scotland

THE annual congress of the Sanitary Association of Scotland has been held during the past week in the Beveridge Hall, Kirkcaldy, under the presidency of Professor John Glaister, M D In his opening address the President discussed the subject of public water supplies in urban and rural communities, dealing more particularly with the conditions necessary to secure a sufficiency of water and to avoid pollution from various possible sources of contamination. Dr T G Nasmyth, medical officer of health of Fifeshire, read a paper on the pollution of rivers He dealt particularly with modern methods of sewage purification as bearing on the condition of rivers and streams and criticised the clauses of the Rivers Prevention Pollution Act. This Act, he said, was so cumbrous and so expensive to put into operation that it had practically become a dead letter He advocated the erection of a separate commission or special department of the Local Government Board to be the supreme authority in dealing with the pollution and other questions affecting the views of the whole country In a paper on small pox hospitals Dr Alexander Johnston, physician superintendent of Ruchill Hospital, Glasgow, discussed the cost of these institutions to the community and argued that such expense would be unnecessary were vaccination and revaccination efficiently enforced. Quoting from recent experiences in Glasgow he showed that the small pox hospital in Glasgow in 1898–99, when not a single case was admitted, cost £1300 to maintain, whilst two years later, when 1700 patients were treated, the cost of maintenance rose to nearly £12,000 Dr Johnston also expressed the opinion that the hospital was a means of spreading infection among the surrounding population and urged that this, as well as the large item of expense, would have been avoided had the local authority power to enforce adequate prophylactic methods. In a discussion on milk supplies Professor Glaister argued against Koch's conclusions regarding the non transmission of bovine tuberculosis to man. His own observations led him to favour a directly opposite view. A question having been raised as to the employment by dairy keepers of servants suffering from various forms of tuberculosis Professor Glaister said he had no doubt that such conduct could be effectively dealt with by a court of law. The meetings of the congress were well attended and proved in every sense highly successful.

Glasgow Royal Infirmary

Dr James Dunlop has resigned his position as assistant physician to the infirmary and Dr John Henderson has been appointed extra dispensary physician.

Sept. 9th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Bicycle Accidents in Dublin.

FATAL bicycle accidents are very frequent in Dublin and its neighbourhood at this season so that not a week passes without a record of serious injury or death. The wife of an English clergyman was recently killed while cycling on Donnybrook road. The explanation of the number of these accidents is to be found firstly in the fact that the bicycle as a means of locomotion is more popular in Dublin than in any other town of the United Kingdom not excluding Coventry which may be looked upon as the birthplace of the cycle, and secondly because the usual laws and regulations have not until quite recently prevailed here. It will surprise English readers of THE LANCET to know that the first announcement that the metropolitan police were about to enforce within the city limits the by laws in connexion with the use of lamps at night—laws that have been put in practice in England for years—appeared here on July 22nd 1902. The first prosecution in connexion with this important regulation took place only the other day when two bicyclists were sentenced to pay a nominal fee for travelling in the dark through the city without lamps.

Armagh Fever Hospital.

At a meeting of the Armagh board of guardians held on Sept. 2nd it was reported that several cases of sore-throat had occurred both in the fever hospital and in the workhouse, caused as the medical officer said by septic poisoning arising from sewage tanks. The reports of the medical officer and of the architect (with his suggestions to remove the unsanitary conditions) were referred to a committee and it was decided to write to the clerk of the urban council and to find out what sum it would accept for the disposal of the union sewage through the new Armagh sewerage scheme.

Small-pox in Belfast.

Belfast is now free from small pox and the stamping-out of the epidemic is due largely to the efforts of Dr A. G Robb, physician to the Fever Hospital, to whom it has been very fairly proposed to grant a bonus of £50 for his arduous duties in connexion with the outbreak

Extraordinary Floods in Belfast

Belfast has been visited by an extraordinary heavy rain storm, which began about 10 o clock on Tuesday Sept. 2nd and continued for about 12 hours, culminating on Wednesday morning in a downpour of really tropical severity the deluge being accompanied by a strong gale and unusually high tides. This visitation in its effects exceeded anything that has ever occurred before and produced a state of things absolutely unprecedented in the history of Belfast. The low lying parts of the city and almost all the business parts of the town were so flooded that many of the streets were impassable and quite a Venetian condition was produced in Belfast an immense deal of injury was done to property and great inconvenience was occasioned. The rainfall for a period of 24 hours was 2·75 inches. Two causes are given for this extraordinary flooding of the city of Belfast—firstly the torrential and altogether unexampled rainfall and, secondly the complete failure of the main drainage scheme of Belfast. I am glad to state that a special meeting of the corporation has been called to consider this latter most important matter

Lisburn Workhouse Hospital.

The Local Government Board has forwarded for the information and consideration of the Lisburn board of guardians a special report which it has received from Dr E. C. Bigger its medical inspector on the condition of the workhouse hospital. The inspector pointed out *inter alia* that there were no convalescent wards, day rooms, or operating rooms and that cases were not classified in the hospital for treatment. Both ambulances were old two-wheeled vehicles and the inspector suggested the substitution of four wheeled machines. The infirmary was not as clean and tidy as it should be. The nursing staff was insufficient, as two day nurses and one night nurse could not carry out all the nursing duties connected with such a large number of patients and at the same time, supervise the lunatic department and the nursery. One additional qualified nurse should be added. There were two padded cells in the lunatic department which should be removed. Iron bedsteads with wire fittings should be provided for the fever hospital. There were no separate wards for consumptive patients. The report concluded by hoping that the inspector's recommendations would be carefully considered.

The Belfast District Asylum.

At a meeting of the committee of the Belfast Asylum, held on Sept. 8th a letter having been read from the Richmond Asylum Committee urging upon the Belfast committee that they should join in the movement for the establishment of a central pathological laboratory in Dublin for lunatic asylums a resolution was passed. That the committee of the Belfast Asylum are of opinion that psycho- and neuro-pathology can be most efficiently and successfully undertaken in connexion with the pathological department of a recognised college or university and having regard to such they consider that the requisite pathological investigation for the Belfast Asylum can be satisfactorily performed in their own laboratory with the coöperation of the Professor of Pathology for Queen's College, whenever external assistance is required. This resolution shows that the Belfast view is entirely against any scheme of centralisation in Dublin. The day for such a scheme is passed

Sept. 9th

PARIS

(FROM OUR OWN CORRESPONDENT.)

The New Director of the Assistance Publique

THE Ministry has chosen M. Mesureur to replace M. Mourier whose death I announced in my last letter to you. The new Director of the Assistance Publique is a politician who was formerly a Deputy for Paris and also for a short time a Minister. At the last general election he was thrown over by the electors and his nomination is evidently a sort of consolation prize given to him by his political friends, who are, as a fact, masters of the Government. M Mesureur who commenced life as a working man, his occupation being that of an embroidery designer knows absolutely nothing about the various complex questions which arise in regard to the Assistance Publique. The director of this administration ought to be at once a philanthropist, a lynx-eyed administrator and an excellent man of business. Other men well known for their labours and their aptitude for these matters were proposed for the post, but it was absolutely necessary for the Government to find a good post for a political friend who is well known for his socialistic revolutionary opinions. It is much to be feared that the choice of the Government, which is being met with lively disapprobation by all the medical men and the whole staff of the Assistance Publique in Paris will do nothing to assist in setting the administration on a sound footing

Various Congresses

At the present time congresses are being held everywhere. At Montauban the French Association for the Advancement of Science is in session. At Grenoble there is a Congress of Neurologists, together with another congress that of Hydrology and Geology. At Grenoble an interesting discussion has been held on the question of *tics*. M Meige and M Feindel, who have just written a remarkable book on this question, have laid before the Congress of Neurologists some very instructive views on the matter. M Meige, together with Professor Brissaud, holds that *tics* are to be distinguished from spasms in that the motions of the former are coördinated, but they are brought about unconsciously and in a purposeless manner As far as treatment goes M Meige recommends exercise before a mirror—that is to say, the patient should practise before a mirror by trying to reproduce voluntarily and slowly the motions of the *tic* When he can do this deliberately and on purpose he may be said to be nearly well At the Montauban Congress the Section of Hygiene has passed some interesting resolutions with regard to alcoholism, the construction of buildings destined for community life such as lycées and hospitals, and the means of combating tuberculosis.

SUDDEN DEATHS OF TWO MEDICAL MEN —Dr C T Aveling of Stamford hill, London after cycling on Sept. 5th, was bathing at Mullion, Cornwall. A young lady who was bathing near him cried out for help and Dr Aveling promptly went to her assistance. Before he reached her and when not out of his depth he sank, it is supposed, from syncope. He was brought in at once by another visitor but life was then extinct Dr Aveling had been an annual visitor at Mullion for some years He was of a genial temperament and was very popular in the little village where much sympathy is felt with his widow and children —Mr Frederick Pratt of Appledore, North Devon, died suddenly whilst visiting a patient on Sept 3rd The deceased received his medical education at St Bartholomew's Hospital and qualified as M.R C S Eng and L.S A. in 1851. He was attached to the Highland Brigade during the Crimean war and received the Crimean medal and clasp, he was also awarded the Turkish medal. Mr Pratt succeeded to his father's practice at Appledore, being one of six sons who were all medical men. The deceased, who was 75 years of age, had been for many years medical officer of health of the Northam district and Trinity surgeon to Lundy Island.

THE Barnstaple friendly societies have just raised over £150 for the North Devon Infirmary and Dispensary

PRESENTATIONS TO MEDICAL PRACTITIONERS —At Negapatam, South India, on August 14th, Mr H W M'Caully Hayes, M.R.C P, L R.C S Edin, L.F P S Glasg, and L M., was presented with a gold signet ring by the members of the St John Ambulance Association class in token of their appreciation of his services as lecturer to the class

DIFFICULTIES UNDER THE NOTIFICATION ACT —We have been requested by the honorary secretary of the Birmingham and District General Medical Practitioners' Union to publish the following resolution which was passed unanimously at a meeting of the union held on Sept 4th —

> That this council considers that the arrangement made by the health committee for one of the medical superintendents of the City Hospital to visit all patients reported to be suffering from chicken pox who are over seven years old is an unwarrantable interference with the liberty of the patient and contrary to the practice of the profession that this action is both unnecessary and improper and should not be undertaken except at the request of and in consultation with, the practitioner in attendance and further that the remarks published in reference to the instance in which it is alleged that no less than six persons in one house were mistakenly treated as suffering from small-pox are libellous, unfair and altogether unjustifiable

A CENTENARIAN — Mrs Macqueeney, *née* Livingstone, a cousin of Dr David Livingstone, the African explorer, has now reached the age of 107 years. She is living at Fishnish, Isle of Mull, under the care of Mrs Fletcher of Glenaros, with whom she was for long a servant. She is feeble and her hearing, which was not good seven years ago, is now completely gone Her memory began to fail many years ago Dr Livingstone, on the occasion of one of his visits to Mull, presented her with a silver brooch, on which her name was inscribed When she was about 35 years of age she married an Irish soldier named Macqueeney Their married life only lasted about four years and their one daughter, now aged 70 years, resides in Glasgow

LORD GREY'S PUBLIC HOUSE TRUST —The active support afforded to this movement in all parts of the kingdom has resulted in the placing in the hands of Lord Grey's Local Trust Companies 35 public houses of which the majority are already opened. In addition to these the People's Refreshment House Association (the pioneer of the movement) of which the Bishop of Chester is president, has acquired 25 houses Of these 60 houses all except six have been taken since 1900 During the next few weeks prospectuses will be issued for additional trust companies for Manchester, Salford and district, Bradford, and the counties of Middlesex Derbyshire, Cheshire, Carnarvonshire, and Staffordshire Those interested in the movement can obtain all information concerning it from the Central Association's Offices at 116, Victoria street, S W

WALTON—RHODES —On July 26th at Klandsfontein South Africa, Captain Henry Beckles G H Walton R.A.M C to Florence Adela daughter of the late Charles Rhodes M.D

WISE—DARBY.—On Sept 10th, at St Mary Hornsey-rise, by the Rev Henry Scott Holland, Robert Wise, M.D., to Adelina Ida daughter of A G Darby

DEATHS

ASHLEY —On Sept 3rd at Sion hill Clifton, Bristol, Ambrose Humphreys Ashley M R.C.S., &c. late H.E.I C S aged 57 years

AVELING —On Sept 6th at Mullion Cornwall, Charles Taylor Aveling M.S M D Lond., F R C.S aged 68 years.

GRANT —On Sept 2nd, at Vinnage Lodge Westbury-on Severn Henry Saunders Grant M R.C.S aged 70

NICOLL.—On August 31st, at Delabole, Cornwall William N S Nicoll M B and C M of Jamaica, West Indies aged 54

POMERY —On Sept. 2nd at Bitterne Southampton James Robert Moriarty Pomery M R C S., aged 75

N.B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

A QUESTION OF FEES

To the Editors of The Lancet

Sirs,—I should like your opinion on the following I was asked to attend an elderly woman in the town in which I reside by a certain individual and did so After her death I was again asked to render my account and along with other charges it was sent to her son who is a medical man in the States of America. He, writing in return to the individual, says it is not the proper thing for one doctor to render an account to another in such a case Was I doing the right thing in sending my bill?

I am Sirs, yours faithfully,
T W

*** The fee should be paid The person calling in our correspondent was liable for the fee and the account was rendered to him —Ed L.

A WATERLESS URINAL

We have received a communication from Mr J T Szek of 12 Montague-place Russell-square London, W C, in which he proposes to do away with the water flushing of urinals He suggests the introduction of a slab in the urinal composed of a porous substance and saturated with an antiseptic such as carbolic acid or its homologues He has submitted a specimen of the porous slab suggested and the disinfectant oil with which it is saturated The proposal raises several important sanitary points Of course, the method suggested neglects the idea that microbes should do the work of destruction and purification since the disinfectant slab is intended to sterilize the urine On the other hand, there is no doubt that water carriage in the case of urine favours fermentation and putrefaction It is a common experience that however well a urinal may be flushed with water it is more or less offensive

DETAILED MEDICAL ACCOUNTS

To the Editors of The Lancet

Sirs,—Patients naturally like to know something of the rate at which they are being charged so I frequently especially with new patients, add in brackets a little detail—e g [60 Ordinary Vts , £7 10s 2 Special Vts 7s 6d Extra Med , 4s 6d] also where I think it necessary the note, ' A Vt to 2 patients = 1½ Vt This plan is only suitable in practices where medicine is not charged for except when excessive in quantity or when supplied apart from visits

I am Sirs yours faithfully,
Woolwich Common Sept 8th, 1902. Theodore Maxwell.

THE RELIEF OF A RUPTURE

To the Editors of The Lancet

Sirs,—Some years ago I got a severe attack of bronchitis—at Nice of all places This was followed by a bronchial cough from which ultimately developed a very prominent hernia in the right inguinal region in fact it seemed to me there must be two openings I immediately went to the best surgical instrument maker I could find was carefully examined had a truss and as that proved of no use I had another But as both failed to keep up the hernia I said to the man, ' Is this all you can do for me? ' and he was sorry to say it was, as he knew of nothing else For a year I bore this inconvenience and irritation with what patience I could and the worst of it was that sometimes, after a fit of coughing I was seized with pain all over the front of the abdomen I never could quite make this out it was evidently connected in some way with the hernia, as it has now disappeared I determined at last to take the matter into my own hands to see what I could do for myself I am not going to weary you or your readers with a detail of all the score of experiments I made with different materials, &c. but I will tell such sufferers at once what I did and what I advise them to do Take a piece of the heaviest sheet-lead say about three inches square and cut it with a pair of scissors until it fits exactly into the space which you wish to be supported This, of course, must be very carefully and accurately done Then when you have got the piece perfectly adapted to the curves of the groin and the scrotum, let it be your model Now take another piece of the sheet-lead—say, four inches square or so—and bevel the edges beyond your model to make all smooth The lead is so pliable that you can bulge it and make it of any size you like Then cut off half the pad of the truss longways and diagonally so that the pressure may be exactly where you want it When you are satisfied with its position on your leaden shield fasten it with a little diamond cement and when dry fold the surplus part of the lead over the edges of the truss and its narrower part so as to keep all firm and secure cover the under surface and the edges with imitation Astrachan fur, also gummed on, and then your protecting pad should be about two and a half inches square or so, but really pear-shaped The thigh strap must of course go on the opposite side and when both straps are properly fixed you will see at once that when the pad is duly pressed against the scrotum nothing can possibly escape—the hernia is absolutely under control. To me the relief was astonishing it was both immediate and complete, while the spasmodic attacks of pain entirely disappeared All I can say is that if any of your readers experiences the same relief he will thank me all the days of his life It may be that this little simple plan may be known to others but it was not to me A small silk pocket-handkerchief may be also put under the pad if need be and the whole worn over the vest By easing the straps I found it very comfortable for night wear I found Burroughs and Wellcome s hazeline cream very useful in relieving the irritation caused by my experiments and also most valuable was a prescription of a celebrated Berlin physician: one-third zinc ointment one-third powdered starch, and one third salicylate of soda. I may observe that a bad case of eczema was cured by this in Gloucestershire which had resisted all other treatment You have my name and address and if any of your readers require any further information, which I think is scarcely necessary, I shall be glad to give it

I am, Sirs, yours faithfully,
August 30th 1902. M D

" OBJECTIONABLE ADVERTISEMENTS '—" THE ENGLISH ILLUSTRATED MAGAZINE "

To the Editors of The Lancet

Sirs —In reply to your correspondent s note in The Lancet of Sept 6th, p 719 my attention was drawn last month to certain advertisements in the *English Illustrated Magazine* I immediately gave orders that they should not appear again, and they are not in the current issue which was published by me on Aug 28th

I am, Sirs, yours faithfully,
Sept 9th 1901 T *Fisher Unwin*

*** Mr T Fisher Unwin s action is only what we should have expected from a publisher of his standing.—Ed L

THE TREATMENT OF ASTHMA

To the Editors of The Lancet

Sirs,—In reply to the inquiry of Rusticus" in The Lancet of Sept 6th (p 720) I would say that Messrs Oppenheimer and Son have in their Neboline Compound No 19 an almost exactly similar preparation to the so-called Tucker s Remedy for Asthma. The compound can be used with either Oppenheimer s 'Nebulizer' or "Aerizer and will be found most effectual in affording relief

I am, Sirs, yours faithfully
William Odell, M.D Durh , F R C S Eng.
Torquay, Sept. 6th, 1902

THE HUMOURS OF CONSCIENTIOUS OBJECTION

At the *North London police-court* on Sept 3rd a *respectably dressed* man, who said that he was a traveller, asked Mr D'Eyncourt for a certificate exempting his child from vaccination He said: "I conscientiously believe that vaccination would be prudential to the health of my child —Mr D'Eyncourt 'What do you say prudential? Surely you do not mean that? —The Applicant (in some confusion): "I can t think of the word —On the advice of the magistrate he sat down to think the matter over and presently returning to the witness box he said: "I conscientiously believe that vaccination would be prejudicial to the health of my child —Mr D'Eyncourt: That is what you intended to say before I suppose?" —The Applicant: 'Yes "—Mr D'Eyncourt "Very well by law you are entitled to have the certificate and you may take it Another *applicant is reported as asking for an exemption certificate for a* child on the ground that he believed ' vaccination to be judicial to my health

ALIQUANDO DORMITAT HOMERUS

The following is from the September number of the London *Polyclinic*:—

> A Bookseller s Blunder.—We have all heard of the sufferer from podagra who purchased a French treatise on Goût in the hope of finding the newest knowledge as to his enemy His blunder has, however been capped by a Reading bookseller, who prints in a catalogue with which he has just favoured us the following:—
>
> 770 MEDICAL —The Anatomy of the Kebla or a Dissection of the Defence of Eastward Adoration, lately published by J Andrews, Vicar of South Newington, in Oxfordshire sm 8vo *hf brown mor*, 3s 6d 1749

THE DUTIES OF A LADY SUPERINTENDENT

To the Editors of The Lancet

Sirs,—You will, I think agree that the following resolution passed by the board of management here a fortnight ago should be read by any intending applicant *for the post of house surgeon to the hospital*: 'That the lady superintendent be given to understand in cases which she believes the house surgeon is not properly carrying out the instructions of the honorary medical staff that it is her duty to report such case at once to the board through the chairman.

I am, Sirs, yours faithfully,
James Campbell, M.B., Ch B Aberd., House Surgeon.
Children s Hospital, Nottingham Sept 9th, 1902.

Mr. F W Waters writes to say that he has sent in his resignation of the post of medical officer of the Sheerness Medical Benefit Society

He would be glad if any person thinking of applying for the appointment would write to him first. The rate of subscription is a halfpenny a week and out of that the medical officer has to find drugs splints, instruments bandages the rent rates and taxes of a surgery; together with the pay of a dispenser and a boy

A CORRESPONDENT who writes from Inglebank, Barker's-lane Ashton-on-Mersey has omitted to sign his letter or to inclose his card

◆

Rufus—Our correspondent is we think at liberty to call himself Doctor" He must however not use the title officially—e.g., he must not sign a death certificate as Rufus, M.D "—but must use his registered qualification

During the week marked copies of the following newspapers have been received —*Buxton Herald, Referee, Nenagh Guardian, Labour Leader Imperial Review Register (Adelaide) Oban Telegraph Engineer Surrey Advertiser Umpire Hertfordshire Mercury Fife Herald, Isle of Wight Herald, Preston Guardian Yorkshire Post Yorkshire Daily Observer &c*

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub-Editor '

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed ' To the Manager*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed London and Westminster Bank, Westminster Branch) should be made payable to the Manager Mr. CHARLES GOOD THE LANCET Offices, 423, Strand, London, W C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND LONDON ENGLAND

An Address

ON

THE PRESENT POSITION OF CHEMICAL PHYSIOLOGY

Delivered before the Physiological Section of the British Association for the Advancement of Science at the meeting at Belfast 1902,

By W D HALLIBURTON, M D Lond, F R S,

PROFESSOR OF PHYSIOLOGY IN KING S COLLEGE, LONDON PRESIDENT OF THE SECTION

THE PRESENT POSITION OF CHEMICAL PHYSIOLOGY

GENTLEMEN —An engineer who desires to understand thoroughly how a machine works must necessarily know its construction. If the machine becomes erratic in its action, and he wishes to put it into proper working order a preliminary acquaintance with its normal structure and function is an obvious necessity If we apply this to the more delicate machinery of the animal body we at once see how a knowledge of function (physiology and pathology) is impossible without a preliminary acquaintance with structure or anatomy It is therefore not surprising—it is indeed in the nature of things—that physiology originated with the great anatomists of the past. It was not until Vesalius and Harvey by tedious dissections laid bare the broad facts of structure that any theorising concerning the uses of the constituent organs of the body had any firm foundation. Important and essential as the knowledge is that can be revealed by the scalpel the introduction and use of the microscope furnished physiologists with a still more valuable instrument. By it much that was before unseen came into view and microscopic anatomy and physiology grew in stature and knowledge simultaneously The weapons in the armoury of the modern physiologist are multitudinous in number and complex in construction and enable him in the experimental investigation of his subject accurately to measure and to record the workings of the different parts of the machinery he has to study But pre-eminent among the instruments stands the test-tube and the chemical operations typified by that simple piece of glass. Herein one sees at once a striking distinction between the mechanism of a living animal and that of a machine like a steam-engine or a watch. It is quite possible to be an excellent watchmaker or to drive a steam engine intelligently without any chemical knowledge of the various metals that enter into its composition In order to set the mechanism right if it goes wrong all the preliminary knowledge which is necessary is of an anatomical nature The parts of which an engine is composed are stable the oil that lubricates it and the fuel that feeds it never become integral parts of the machinery But with the living engine all this is different. The parts of which it is made take up the nutriment or fuel and assimilate it, thus building up new living substance to replace that which is destroyed by the wear and tear associated with activity This condition of unstable chemical equilibrium is usually designated metabolism, and metabolism is the great and essential attribute of a living as compared with a non living thing

It seems childish at the present day and before such an audience as this to point out how essential it is to know the chemical structure as well as the anatomical structure of the component parts of the body, But the early anatomists to whom I have alluded had no conception of the connexion of the two sciences Speaking of Vesalius, Sir Michael Foster says The great anatomist would no doubt have made use of his bitterest sarcasms had someone assured him that the fantastic school which was busy with occult secrets and had hopes of turning dross into gold would one day join hands in the investigation of the problems of life with the exact and clear anatomy so dear to him." Nor did Harvey any more than Vesalius, pay heed to chemical learning The scientific men of his time ignored and despised the beginning of that chemical knowledge which in later years was to become one of the foundations of physiology and the mainstay of the art of medicine The earliest to recognise this important connexion was one whose name is usually associated more with charlatanry than with truth—namely Paracelsus and 50 years after the death of that remarkable and curious personality his doctrines were extended and developed by van Helmont. In spite, however of van Helmont s remarkable insight into the processes of digestion and fermentation, his work was marred by the mysticism of the day which called in the aid of supernatural agencies to explain what could not otherwise be fully comprehended

In the 250 years that have intervened between the death of van Helmont and the present day alchemy became a more and more exact science and changed its name to chemistry and a few striking names stand out of men who were able to take the new facts of chemistry and to apply them to physiological uses. Of these one may mention Mayow Lower Boerhaave Réaumur Borelli, Spallanzani, and Lavoisier Mulder in Holland and Liebig in Germany bring us almost to the present time, and I think they may be said to share the honour of being regarded as the father of modern chemical physiology This branch of science was first placed on a firm basis by Wöhler when he showed that organic compounds can be built out of their elements in the laboratory and his first successful experiments in connexion with the comparatively simple substance urea have been followed by numberless others which have made organic chemistry the vast subject it is to-day

Sir Michael Foster s book on the History of Physiology from which I have already quoted treats of the older workers who laid the foundations of our science and whose names I have not done much more than barely mention Those interested in the giants of the past should consult it. But what I propose to take up this morning is the work of those who have during more recent days been engaged in the later stages of the building The edifice is far from completion even now It is one of the charms of physiological endeavour that as the older areas yield their secrets to the explorers new ones are opened out which require equally careful investigation. If even a superficial survey of modern physiological literature is taken one is at once struck with the great preponderance of papers and books which have a chemical bearing. In this the physiological journals of to-day contrast very markedly with those of 30 20 or even 10 years ago The sister science of chemical pathology is making similar rapid strides. In some universities the importance of biological chemistry is recognised by the foundation of chairs that deal with that subject alone and though in the United Kingdom owing mainly to lack of funds, this aspect of the advance of science is not very evident, there are signs that the date cannot be far distant when every well-equipped university or university college will follow the example set us at many seats of learning on the continent and at Liverpool With these introductory remarks let me now proceed to describe what appear to me to be the main features of chemical physiology at the present time.

The first point to which I shall direct your attention is the rapid way in which chemical physiology is becoming an exact science. Though it is less than 20 years since I began to teach physiology I can remember perfectly well a time when those who devoted their work to the chemical side of the science might almost be counted on the fingers of one hand and when chemists looked with scarcely veiled contempt on what was at that time called physiological chemistry, they stated that physiologists dealt with messes or impure materials and therefore anything in the nature of correct knowledge was not possible. There was a good deal of truth in these statements and if physiologists to-day cannot quite say that they have changed all that they can at any rate assert with truth that they are changing it This is due to a growing *rapprochement* between chemists and physiologists Many of our younger physiologists now go through a thorough preliminary chemical training and on the other hand there is a growing number of chemists—of whom Emil Fischer may be taken as a type—who are beginning to recognise the importance of a systematic study of substances of physiological interest. A very striking instance of this is seen in the progress of our knowledge of the carbohydrates which has culminated in the actual synthesis of several members of the sugar group Another instance is seen in the accurate information we now possess of the constitution of uric acid When Miescher began his work on the chemical composition of the nuclei of cells and separated from them the material he called nuclein he little foresaw the wide practical application of his work. We now know that it is in the metabolism of cell nuclei that we have to look for the oxidative formation of uric acid and other substances of the purine family Already the chemical relationships of uric acid and nuclein have taught practical physicians some of the secrets that underlie the occurrence of gout and allied disorders

With the time at my disposal it would be impossible to discuss all the chemico vital problems which the physiologists of the present day are attempting to solve, but there is one subject at which many of them are labouring which seems to me to be of supreme importance—I mean the chemical constitution of proteid or albuminous substances Proteids are produced only in the living laboratory of plants and animals, proteid metabolism is the main chemical attribute of a living thing, proteid matter is the all important material present in protoplasm But in spite of the overwhelming importance of the subject chemists and physiologists alike have far too long fought shy of attempting to unravel the constitution of the proteid molecule This molecule is the most complex that is known it always contains five, and often six, or even seven, elements The task of thoroughly understanding its composition is necessarily vast and advance slow But little by little the puzzle is being solved, and this final conquest of organic chemistry, when it does arrive, will furnish physiologists with new light on many of the dark places of physiological science.

The revival of the vitalistic conception in physiological work appears to me a retrograde step To explain anything we are not fully able to understand in the light of physics and chemistry by labeling it as vital or something we can never hope to understand is a confession of ignorance and, what is still more harmful, a bar to progress It may be that there is a special force in living things that distinguishes them from the inorganic world. If this is so, the laws that regulate this force must be discovered and measured, and I have no doubt that those laws when discovered will be found to be as immutable and regular as the force of gravitation I am, however, hopeful that the scientific workers of the future will discover that this so-called vital force is due to certain physical or chemical properties of living matter which have not yet been brought into line with the known chemical and physical laws that operate in the inorganic world, but which, as our knowledge of chemistry and physics increases, will ultimately be found to be subservient to such laws

Let me take as an example the subject of osmosis The laws which regulate this phenomenon through dead membranes are fairly well known and can be experimentally verified, but in the living body there is some other manifestation of force which operates in such a way as to neutralise the known force of osmosis Is it necessary to suppose that this force is a new one? May it not rather be that our much vaunted knowledge of osmosis is not yet complete? It is quite easy to understand why a dead and a living membrane should behave differently in relation to substances that are passing through them. The molecules of the dead membrane are, comparatively speaking, passive and stable, the molecules in a membrane made of living cells are in a constant state of chemical integration and disintegration, they are the most unstable molecules we know Is it to be expected that such molecules would allow water, or substances dissolved in water, to pass between them and remain entirely inactive? The probability appears to me to be all the other way, the substances passing, or attempting to pass, between the molecules will be called upon to participate in the chemical activities of the molecules themselves, and in the building up and breaking down of the compounds so formed there will be a transformation of chemical energy and a liberation of what looks like a new force. Before a physicist decides that his knowledge of osmosis is final let him attempt to make a membrane of some material which is in a state of unstable chemical equilibrium, a state in some way comparable to what is called metabolism in living protoplasm. I cannot conceive that such a task is insuperable, and when accomplished, and the behaviour of such a membrane in an osmometer or dialyser is studied, I am convinced that we shall find that the laws of osmosis as formulated for such dead substances as we have hitherto used will be found to require revision.

Such an attitude in reference to vital problems appears to be infinitely preferable to that which too many adopt of passive content, saying that the phenomenon is vital and there is an end of it. When a scientific man says this or that vital phenomenon cannot be explained by the laws of chemistry and physics, and therefore must be regulated by laws of some other nature, he most unjustifiably assumes that the laws of chemistry and physics have all been discovered. He forgets, for instance, that such an important detail as the constitution of the proteid molecule has still to be made out. The recent history of science gives an emphatic denial to such a supposition All my listeners have within the last few years seen the discovery of the Roentgen rays and the modern development of wireless telegraphy On the chemical side we have witnessed the discovery of new elements in the atmosphere and the introduction of an entirely new branch of chemistry called physical chemistry With such examples ready to our hands, who can say what further discoveries will not shortly be made, even in such well worked fields as chemistry and physics?

The mention of physical chemistry brings me to what I may term the second head of my discourse, the second striking characteristic of modern chemical physiology this is the increasing importance which physiologists recognise in a study of inorganic chemistry The materials of which our bodies are composed are mainly organic compounds, among which the proteids stand out as pre eminently important, but everyone knows that there are many substances of the mineral or inorganic kingdom present in addition I need hardly mention the importance of water, of the oxygen of the air, and of salts like sodium chloride and calcium phosphate.

The new branch of inorganic chemistry called physical chemistry has given us entirely new ideas of the nature of solutions, and the fact that electrolytes in solution are broken up into their constituent ions is one of fundamental importance One of the many physiological aspects of this subject is seen in a study of the action of mineral salts in solution on living organisms and parts of organisms. Many years ago Dr Ringer showed that contractile tissues (heart, cilia, &c.) continue to manifest their activity in certain saline solutions Howell goes so far as to say, and probably correctly say, that the cause of the rhythmical action of the heart is the presence of these inorganic substances in the blood or lymph which usually bathes it. The subject has more recently been taken up by Loeb and his colleagues at Chicago they confirm Ringer's original statements but interpret them now as ionic action Contractile tissues will not contract in pure solutions of non-electrolytes like sugar or albumin But different contractile tissues differ in the nature of the ions which are their most favourable stimuli An optimum salt solution is one in which stimulating ions, like those of sodium, are mixed with a certain small amount of those which, like calcium, restrain activity Loeb considers that the ions act because they affect either the physical condition of the colloidal substances (proteid, &c.) in protoplasm or the rapidity of chemical processes. Amœboid movement, ciliary movement, the contraction of muscle, cell division, and karyokinesis all fall into the same category as being mainly dependent on the stimulating action of ions Loeb has even gone so far as to consider that the process of fertilisation is mainly ionic action, he denies that the nuclein of the male cell is essential, but asserts that all it does is to act as the stimulus in the due adjustment of the proportions of the surrounding ions, and supports this view by numerous experiments on ova in which without the presence of spermatozoa he has produced larvæ by merely altering the saline constituents and so the osmotic pressure of the fluid that surrounds them. Whether such a sweeping and almost revolutionary notion will stand the test of further verification must be left to the future, so also must the equally important idea that nervous impulses are to be mainly explained on an electrolytic basis But whether or not all the details of such work will stand the test of time, the experiments I have briefly alluded to are sufficient to show the importance of physical chemistry to the physiologist, and they also form a useful commentary on what I was saying just now about vitalism. Such eminently vital phenomena as movement and fertilisation are to be explained in whole or in part as due to the physical action of inorganic substances Are not such suggestions indications of the undesirability of postulating the existence of any special mystic vital force?

I have spoken up to this point of physical chemistry as a branch of inorganic chemistry, there are already indications of its importance also in relation to organic chemistry Many eminent chemists consider that the future advance of organic chemistry will be on the new physical lines It is impossible to forecast where this will lead us, suffice it to say that not only physiology but also pathology pharmacology and even therapeutics, will receive new accessions to knowledge the importance of which will be enormous.

I have now briefly sketched what appear to me to be the two main features of the chemical physiology of to-day and the two lines, organic and inorganic along which I believe it will progress in the future. Let me now press upon you the importance in physiology as in all experimental sciences, of the necessity first of bold experimentation and secondly of bold theorising from experimental data. Without experiment all theorising is futile, the discovery of gravitation would never have seen the light if laborious years of work had not convinced Newton that it could be deduced from his observations The Darwinian theory was similarly based upon data and experiments which occupied the greater part of its author s lifetime to collect and to perform. Pasteur in *France and Virchow in Germany supply other instances of* the same devotion to work which was followed by the promulgation of wide-sweeping generalisations. And after all it is the general law which is the main object of research isolated facts may be interesting and are often of value, but it is not until facts are correlated and the discoverers ascertain their inter relationships that anything of epoch making importance is given to the world. It is, however frequently the case that a thinker with keen insight can see the general law even before the facts upon which it rests are fully worked out Often such bold theorisers are right, but even if they ultimately turn out to be wrong or only partly right, they have given to their fellows some general idea on which to work If the general idea is incorrect it is important to prove it to be so in order to discover what is right later No one has ever seen an atom or a molecule, yet who can doubt that the atomic theory is the sheet anchor of chemistry? Mendeleeff formulated his periodic law before many of the elements were discovered yet the accuracy of this great generalisation has been such that it has actually led to the discovery of some of the missing elements.

I purpose to illustrate these general remarks by a brief *allusion to two typical sets of researches* carried out during recent years in the region of chemical physiology I do not pretend that either of them has the same overwhelming importance as the great discoveries I have alluded to but I am inclined to think that one of them comes very near to that standard. The investigations in question are those of Ehrlich and of Pawlow The work of Ehrlich mainly illustrates the useful part played by bold theorising the work of Pawlow that played by the introduction of new and bold methods of experiment.

I will take Pawlow first. This energetic and original Russian physiologist has by his new methods succeeded in throwing an entirely new light on the processes of *digestion.* Ingeniously devised surgical operations have enabled him to obtain the various digestive juices in a state of absolute purity and *in large quantity* *Their composition* and their actions on the various foodstuffs have thus been ascertained in a manner never before accomplished an apparently unfailing resourcefulness in devising and adapting experimental methods has enabled him and his fellow workers to discover the paths of the various nerve impulses by which secretion in the alimentary canal is regulated and controlled The importance of the psychical element in the process of digestion has been experimentally verified. If I were asked to point out what I considered to be the most important outcome of all this painstaking work, I should begin my answer by a number of negatives and would say, not the discovery of the secretory nerves of the stomach or pancreas, not the correct analysis of the gastric juice or the fact that the intestinal juice has most useful digestive functions all of these are *discoveries of* which anyone might have been rightly proud but after all they are more or less isolated facts. The main thing that Pawlow has shown is that digestion is not a succession of isolated acts but each one is related to its predecessor and to that which follows it the process of digestion is thus a continuous whole for example the acidity of the gastric juice provides for a delivery of pancreatic juice in proper quantity into the intestine the intestinal juice *acts upon the pancreatic,* and so enables the latter to perform its powerful actions. I am afraid that this example, as I have tersely stated it presents the subject rather inadequately, but it will serve to show what I mean. Further, the composition of the various juices is admirably adjusted to the needs of the organism when there is much proteid to be digested the proteolytic activity of the juices secreted is correspondingly high, and the same is true for the other constituents of the food It is such general conclusions as these the correlation of isolated facts leading to the formulation of the law that the digestive process is continuous in the sense I have indicated and adapted to the needs of the work to be done, that constitute the great value of the work from the Russian laboratory Work of this sort is sure to stimulate others to fill in the gaps and complete the picture, and already has borne fruit in this direction. It has, for instance, in Starling's hands led to the discovery of a chemical stimulus to pancreatic secretion This is formed in the intestine as the result of the action of the gastric acid and taken by the blood stream to the pancreas. Whether this *secretin,* as it is called, may be one of a group of similar chemical stimuli which operate in other parts of the body has still to be found out

The other series of researches to which I referred are those of Ehrlich and his colleagues and followers on the subject of *immunity* This subject is one of such importance to every one of us that I am inclined to place the discovery on a level with those great discoveries of natural laws to which I alluded at the outset of this portion of my address. I hesitate to do so yet, because many of the details of the theory still await verification But up to the present all is working in that direction and Ehrlich s ideas illustrate the value of bold theorising in the hands of clear-sighted and far seeing individuals. But when I say that the doctrine is bold, I do not mean to infer that the experimental facts are scanty they are just the reverse But in the same way that a chemist has never seen an atom and yet he believes atoms to exist, so no one has yet ever seen a toxin or an antitoxin in a state of purity and yet we know they exist and this knowledge promises to be of incalculable benefit to suffering *humanity*

It may not be uninteresting to state briefly for the benefit of those to whom the subject is new the main facts and an outline of the theory which is based upon them We are all aware that one attack of many infective maladies protects us against another attack of the same disease. The person is said to be *immune* either partially or completely against that disease. Vaccination produces in a patient an attack of cowpox or vaccinia. This disease is related to small pox and some still hold that it is small pox modified and rendered less malignant by passing through the body of a calf At any rate an attack of vaccinia renders a person immune to small pox or variola for a certain number of years. Vaccination is an instance of what is called *protective inoculation,* which is now practised with more or less success in reference to other diseases like plague and typhoid fever The study of immunity has also rendered possible what may be called *curative inoculation* or the injection of antitoxic material as *a cure for* diphtheria, tetanus snake poisoning &c. The power the blood possesses of slaying bacteria was first discovered when the effort was made to grow various kinds of bacteria in it it was looked upon as probable that blood would prove a suitable soil or *medium for this purpose.* It was found in some instances to have exactly the opposite effect. The chemical characters of the substances which kill the bacteria are not fully known indeed the same is true for most of the substances we have to speak of in this connexion Absence of knowledge on this particular point has not, however prevented important discoveries from being made So far as is known at present, the substances in question are proteid in nature. The bactericidal powers of blood are *destroyed* by heating it for an hour at 56° C. Whether the substances are enzymes is a disputed point So also is the question whether they are derived from the leucocytes, the balance of evidence appears to me to be in favour of this view in many cases at any rate, and phagocytosis becomes more intelligible if this view is accepted. The substances, whatever be their source or their chemical nature are sometimes called alexins but the more usual name now applied to them is that of *bacterio lysins.* Closely allied to the bactericidal power of blood or blood serum is its globulicidal power By this one means that the blood serum of one animal has the power of dissolving the red blood-corpuscles of another species. If the serum of one animal is injected into the blood stream of an animal of another species the result is a destruction of its red *corpuscles,* which may be so excessive as to lead to the passing of the liberated hæmoglobin into the urine (hæmoglobinuria) The substance or substances in the serum that possess this property are called *hæmolysins* and though there is some doubt whether bacteriolysins and hæmo-lysins are absolutely identical there is no doubt that they are closely related substances

Another interesting chemical point in this connexion is the fact that the bactericidal power of the blood is closely related to its alkalinity Increase of alkalinity means increase of bactericidal power Venous blood contains more diffusible alkali than arterial blood and is more bactericidal, dropsical effusions are more alkaline than normal lymph and kill bacteria more easily In a condition like diabetes, when the blood is less alkaline than it should be, the susceptibility to infectious disease is increased Alkalinity is probably beneficial because it favours those oxidative processes in the cells of the body which are so essential for the maintenance of healthy life Normal blood possesses a certain amount of substances which are inimical to the life of our bacterial foes But suppose a person gets run down, everyone knows that he is then liable to "catch anything" This coincides with a diminution in the bactericidal power of his blood But even a perfectly healthy person has not an unlimited supply of bacterio lysin, and if the bacteria are sufficiently numerous he will fall a victim to the disease they produce Here, however, comes in the remarkable part of the defence In the struggle he will produce more and more bacterio-lysin, and if he gets well it means that the bacteria are finally vanquished and his blood remains rich in the particular bacteriolysin he has produced and so will render him immune to further attacks from that particular species of bacterium Every bacterium seems to cause the development of a specific bacterio lysin Immunity can more conveniently be produced gradually in animals, and this applies, not only to the bacteria, but also to the toxins they form If, for instance, the bacilli which produce diphtheria are grown in a suitable medium they produce the diphtheria poison, or toxin, much in the same way that yeast-cells will produce alcohol when grown in a solution of sugar Diphtheria toxin is associated with a proteose, as is also the case with the poison of snake venom. If a certain small dose called a "lethal dose" is injected into a guinea pig the result is death But if the guinea pig receives a smaller dose it will recover, a few days after it will stand a rather larger dose and this may be continued until after many successive gradually increasing doses it will finally stand an amount equal to many lethal doses without any ill effects The gradual introduction of the toxin has called forth the production of an antitoxin. If this is done in the horse instead of the guinea pig the production of antitoxin is still more marked and the serum obtained from the blood of an immunised horse may be used for injecting into human beings suffering from diphtheria and rapidly cures the disease The two actions of the blood, antitoxic and antibacterial, are frequently associated but may be entirely distinct.

The antitoxin is also a proteid probably of the nature of a globulin, at any rate, it is a proteid of a larger molecular weight than a proteose This suggests a practical point In the case of snake bite the poison gets into the blood rapidly owing to the comparative ease with which it diffuses, and so it is quickly carried all over the body In treatment with the antitoxin or antivenin speed is everything if life is to be saved, injection of this material under the skin is not much good, for diffusion into the blood is too slow It should be injected straight away into a blood vessel There is no doubt that in these cases the antitoxin neutralises the toxin much in the same way that an acid neutralises an alkali. If the toxin and antitoxin are mixed in a test tube, and time allowed for the interaction to occur, the result is an innocuous mixture The toxin however, is merely neutralised, not destroyed, for if the mixture in the test-tube is heated to 68° C the antitoxin is coagulated and destroyed and the toxin remains as poisonous as ever

Immunity is distinguished into *active* and *passive* Active immunity is produced by the development of protective substances in the body, passive immunity by the injection of a protective serum Of the two the former is the more permanent. *Ricin* the poisonous proteid of castor oil seeds, and *abrin* that of the Jequirity bean also produce when gradually given to animals an immunity due to the production of antiricin and antiabrin respectively Ehrlich's hypothesis to explain such facts is usually spoken of as the *side-chain theory* of immunity He considers that the toxins are capable of uniting with the protoplasm of living cells by possessing groups of atoms like those by which nutritive proteids are united to cells during normal assimilation. He terms the e *haptophor* groups and the groups to which these are attached in the cells he terms *receptor* groups The introduction of a toxin stimulates an excessive production of receptors, which are finally thrown out into the circulation, and the free circulating receptors constitute the antitoxin The comparison of the process to assimilation is justified by the fact that non toxic substances like milk introduced gradually by successive doses into the blood stream cause the formation of anti substances capable of coagulating them

Up to this point I have spoken only of the blood, but month by month workers are bringing forward evidence to show that other cells of the body may by similar measures be rendered capable of producing a corresponding protective mechanism

One further development of the theory I must mention At least two different substances are necessary to render a serum bactericidal or globulicidal. The bacterio-lysin or hæmolysin consists of these two substances One of these is called the *immune body*, the other the *complement* We may illustrate the use of these terms by an example The repeated injection of the blood of one animal—e g, the goat—into the blood of another animal—e g, a sheep—after a time renders the latter animal immune to further injections, and at the same time causes the production of a serum which dissolves readily the red blood corpuscles of the first animal The sheep's serum is thus hæmolytic towards goat's blood-corpuscles This power is destroyed by heating to 56° C for half an hour, but returns when fresh goat's serum is added The specific immunising substance formed in the sheep is called the immune body, the ferment like substance destroyed by heat is the complement. The latter is not specific since it is furnished by the blood of non immunised animals, but it is nevertheless essential for hæmolysis Ehrlich believes that the immune body has two side groups—one which connects with the receptor of the red corpuscles and one which unites with the haptophor group of the complement and thus renders possible the ferment-like action of the complement on the red corpuscles Various antibacterial serums which have not been the success in treating disease they were expected to be are probably too poor in complement, though they may contain plenty of the immune body Quite distinct from the bactericidal, globulicidal, and antitoxic properties of blood is its agglutinating action This is another result of infection with many kinds of bacteria or their toxins The blood acquires the property of rendering immobile and clumping together the specific bacteria used in the infection The test applied to the blood in cases of typhoid fever and generally called Widal's reaction depends on this fact The substances that produce this effect are called *agglutinins* They also are probably proteid like in nature, but are more resistant to heat than the lysins Prolonged heating to over 60° C is necessary to destroy their activity

Lastly, we come to a question which more directly appeals to the physiologist than the preceding, because experiments in relation to immunity have furnished us with what has hitherto been lacking—a means of distinguishing human blood from the blood of other animals The discovery was made by Tchistovitch (1899) and his original experiment was as follows rabbits, dogs, goats, and guinea pigs were inoculated with eel serum which is toxic, he thereby obtained from these animals an antitoxic serum But the serum was not only antitoxic, but produced a precipitate when added to eel serum but not when added to the serum of any other animal, in other words, not only has a specific antitoxin been produced but also a specific *precipitin* Numerous observers have since found that this is a general rule throughout the animal kingdom including man If, for instance, a rabbit is treated with human blood the serum ultimately obtained from the rabbit contains a specific precipitin for human blood, that is to say, a precipitate is formed on adding such a rabbit's serum to human blood, but not when added to the blood of any other animal [2] The great value of the test is its delicacy it will detect the specific blood when it is greatly diluted, after it has been dried for weeks, or even when it is mixed with the blood of other animals

I have entered into this subject at some length because it so admirably illustrates the kind of research which is now in progress, it is also of interest to others than mere physiologists I have not by an means exhausted the subject, but for fear I may exhaust my audience let me hasten to a conclusion. I began by eulogising the progress of the branch of science on which I have elected to speak to you. Let me conclude with a word of warning on the danger of over specialisation. The ultra specialist is apt to become narrow, to confine himself so closely to his own groove that he forgets to notice what is occurring in the parallel and inter crossing grooves of others But those who devote themselves to the chemical side of physiology run but little danger of this evil. The subject cannot be studied apart from other branches of physiology so closely are both branches and roots intertwined. As an illustration of this may I be permitted to speak of some of my own work? During the past few years the energies of my laboratory have been devoted to investigations on the chemical side of nervous activity and I have had the advantage of coöperating to this end with a number of investigators, of whom I may particularly mention Dr F W Mott and Dr T G Brodie But we soon found that any narrow investigation of the chemical properties of nervous matter and the changes this undergoes during life and after death was impossible. Our work extended in a pathological direction so as to investigate the matter in the brains of those suffering from nervous disease, it extended in a histological direction so as to determine the chemical meaning of various staining reactions presented by normal and abnormal structures in the brain and spinal cord it extended in an experimental direction in the elucidation of the phenomena of fatigue and to ascertain whether there was any difference in medullated and non medullated nerve-fibres in this respect it extended into what one may call a pharmacological direction in the investigation of the action of the poisonous products of the breakdown of nervous tissues. I think I have said enough to show you how intimate are the connexions of the chemical with the other aspects of physiology and although I have given you but one instance that which is freshest to my mind the same could be said for almost any other well planned piece of research work of a bio-chemical nature.

---

[2] There may be a slight reaction with the blood of allied animals, for instance with monkey's blood in the case of man

We have now before us the real work of the section, the reading hearing and seeing the researches which will be brought forward by members of the Association and I must, in thanking you for your attention, apologise for the length of time I have kept you from these more important matters.

A Clinical Lecture

ON

ACUTE INFANTILE BRONCHO-PNEUMONIA (BRONCHO-PNEUMONITIS)

BASED ON THE CLINICAL, PATHOLOGICAL, AND HÆMATOLOGICAL PHENOMENA OBSERVED IN THREE FATAL CASES.

Delivered in the Glasgow Royal Infirmary on Feb 10th 1902

By JOHN LINDSAY STEVEN, M.D,
F F P S GLASG,

PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY; LECTURER ON THE PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW; EXTRA HONORARY PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN GLASGOW HONORARY LIBRARIAN FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW

THERE is, perhaps no disease of infancy and childhood concerning which it is more difficult to form a precise conception as to etiology pathology and diagnosis than that to which the terms "broncho-pneumonia," "lobular pneumonia," and "capillary bronchitis" have indifferently and on the whole with fair accuracy as regards the essential phenomena, been applied. As to the clinical phenomena of broncho-pneumonia it may perhaps be admitted that there is a general uniformity of the more prominent symptoms in the different cases met with in practice, especially in the acute forms but when the etiology the clinical course, the morbid anatomy the histology and the bacteriology of the disease are considered we find ourselves face to face with many and difficult problems. Are we dealing with one morbid condition of the respiratory system or with several? Are the different types or forms which we meet with in practice separate diseases or mere variations of one and the same morbid process? Why do some cases tend rapidly to death in a few days and others as rapidly to get well? Are the cases which from the first are subacute and lead on to a long course of chronic respiratory illness, not infrequently ending fatally or in pulmonary tuberculosis essentially the same in etiology and pathology as the more acute forms? Are broncho-pneumonia and lobar pneumonia the same or different? These are a few of the problems which are constantly suggesting themselves to every practitioner of experience, and it must be admitted that, even with our greatly increased knowledge of the pathology and bacteriology of the conditions concerned no very satisfactory solutions are yet possible. These considerations, then sufficiently explain to you why I have determined to make the three fatal cases of acute infantile broncho-pneumonia which we have recently watched in the ward, and two of which we have followed to the post-mortem theatre, the text of a clinical lecture on this very common and exceedingly fatal disease. Let me first of all by means of brief summaries of the reports in the ward journal recall the three cases to your memories.

CASE I.—The patient, aged nine months, was admitted to Ward 8 on Nov 19th 1901 and died on the 20th. His mother took him out, as she was in the habit of doing on the evening of Nov 16th between 7 and 8 o'clock and she thinks he caught cold on that occasion, as next day he was "running at the nose" and his bowels were constipated, the latter condition, however having been present for some days before Her medical attendant prescribed a powder for the constipation, but no cough or difficulty of breathing was noted till the day before admission when the mother felt a "crackling" if she placed her hand over the child's chest. At this time, too the abdomen was much swollen. The cough was not very frequent or vigorous The patient had always been rather a delicate child suffering more or less from cough, and he had "green diarrhœa" very severely when he was a month old. Of a family of eight children three died in infancy from "lung trouble" or "dregs of the measles" On admission the patient was very ill the face being pallid and livid, and the respirations very shallow and rapid numbering from 80 to 94 per minute, and occasionally somewhat of the Cheyne-Stokes type—i.e. shallow and forced breathing alternating, the alæ nasi dilated vigorously the intercostal spaces were sucked in during inspiration, and the pulse was so rapid small and thready that it could not be counted The shape of the head suggested a rachitic diathesis and the temperature during residence ranged between 103° and 104° F Over the right apex in front there was a dull, or dull tympanitic, note with intense tubular breathing latterly associated with medium crackling râles. At the right base posteriorly there was marked dulness the respiratory murmur was harsh but not tubular and there were numerous crackling râles with inspiration. Percussion over the left lung was generally resonant, except in the infra spinous region behind where it was impaired, and râles were nowhere so prominent as on the right side The abdomen was somewhat distended and the bowels were loose, the motions being light yellow in colour but not very copious. Two blood-counts were made by my resident, Dr J Scott with the following results On Nov 19th, 1901 examined in the fresh state the red blood corpuscles formed characteristic rouleaux. Hæmoglobin, 60 per cent. red blood corpuscles 2,276,000 and white blood corpuscles, 15 212 A differential count of the leucocytes gave these results polymorphonuclear 79 5 per cent. lymphocytes, 18 6 per cent. and large mononuclear 1·9 per cent. On Nov 20th at 12 noon hæmoglobin 60 per cent. red blood corpuscles, 2,037 500 and white blood corpuscles, 12,000 Death took place at 8 P M You witnessed the post-mortem examination of this case on Nov 21st, 1901, and I shall now read to you Dr Charles Workman's report.

Summary—Pleurisy of right side pericarditis; partial collapse of left lung *External appearances*—A fairly well nourished body, with rather large head and open fontanelles. *Thorax*—The left lung is free from pleural adhesions. The right lung is adherent over most of the lower lobe from a fresh fibrinous pleurisy The upper lobe of the right lung is in part consolidated so that a portion sinks at once in water This consolidation appears to be due to œdema for the most part and it does not appear congested. The left lung shows some small areas of collapse but otherwise appears healthy The pericardium shows a well-marked fibrinous pericarditis but contains very little fluid

The heart presents remarkably healthy characters *Abdomen* —The stomach is normal in size and contains a quantity of coagulated milk Its mucous membrane is in a condition of catarrh There is slight general catarrh of the intestine and the Peyer's patches near the ileo-cæcal valve are somewhat congested The liver is slightly enlarged but otherwise healthy The spleen is much enlarged and congested The kidneys present very healthy characters The mesenteric lymphatic glands are perhaps unduly prominent but are not definitely diseased

Dr Walter K. Hunter has made a series of sections of the lungs in this case which I shall shortly describe to you, and you will then see that the consolidation at the right apex was inflammatory and not œdematous and that the so-called "small areas of collapse" are in reality small areas of inflammation The bacteriology of the case, which was investigated by Mr D McCrorie, I will speak of at a later part of the lecture.

CASE 2.—The patient, aged 15 months, was admitted to Ward 8 on Dec 2nd, 1901, and died on the 6th. About two months before admission he suffered from an attack of "pneumonia," for which he was treated at the Sick Children's Dispensary and from which he had apparently recovered about Nov 13th. This illness, however left some cough behind and on the evening of Nov 30th it was observed that he had suddenly become much worse. He refused food, moaned a great deal, and became very short of breath. His skin was very hot and his cough was frequent but not violent or accompanied by any expectoration The day before admission he was seen at the dispensary by Dr J W Findlay and admitted as a case of acute pneumonia. During residence in the ward the temperature, taken four hourly, ranged between 101° and 104° F , but on the first night it was as high as 104 8° , the pulse averaged 145 per minute, with one maximum of 176 and two minima of 132 , the respirations averaged 76, with one maximum of 94 and one minimum of 61 The breathing was all along very shallow and the cough, though frequent, was not violent The pulmonary physical signs were chiefly confined to the right lung , over the right side of the thorax there were diminished movement and dulness in the right infra clavicular and right infrascapular regions with resonance in the right axillary region. Over the dull areas of the right side the respiratory murmur was always audible and of tubular type , and during the last two days over the whole right lung, but particularly at the base, numerous coarse crackling râles were heard. Over the left lung the respiratory murmur was everywhere of vesicular though harsh character and no special dulness or crackling râle was at any time noted The question of empyema at the right base was raised on Dec 3rd, 1901, but in view of the abundant breath sound over the dull area I decided not to use the exploring needle Pale lividity of the face was marked throughout and on the evening of the 5th swelling of the hands was observed. On the morning of the 6th the lividity was much more pronounced and there was very marked œdema of the hands and arms, while there was no trace of dropsy in the lower limbs or trunk I regarded this localised dropsy of the upper limbs as indicative of severe pleural involvement, probably empyema, and so I explored the right side of the chest in three different spots but with quite negative results The child died in the afternoon. Blood counts by Dr Scott — Dec 2nd, 1901 hæmoglobin, 78 per cent. , red blood corpuscles, 3,750,000 , and white blood corpuscles, 12,500 Dec. 3rd hæmoglobin, 65 per cent , red blood corpuscles, 17,921 and 8192 at midnight , and lymphocytes, 37 per cent. Dec. 4th hæmoglobin, 65 per cent. , the white blood corpuscles in seven counts ranged from 6400 in the morning to 13 800 at midnight, the lymphocytes from 38 to 50 per cent Dec. 5th hæmoglobin, 58 per cent. , white blood corpuscles, 16 000 , and lymphocytes 33 per cent The average of these observations gives us 12,485 white blood corpuscles per cubic millimetre and 39 5 per cent of lymphocytes, with a maximum of 17,921 leucocytes and a minimum of 6403 at midnight. On Dec 9th you saw the post-mortem examination of this child and I now read to you Dr Workman's report —

Summary —Double pleurisy fibrinous catarrhal pneumonia of right lung *External appearances* —A fairly well-developed and somewhat emaciated body Post mortem rigidity has passed off *Thorax.*—On opening the thorax the posterior parts of both lower lobes of the lungs are found to be covered with a thick layer of recent fibrin The right lower lobe is collapsed so that it will sink at once in water The upper lobe presents a large cavity or cyst which is lined by a smooth non inflammatory membrane and is partially subdivided by septa which are covered by the same smooth membrane From this appearance this cavity is of old standing and is probably congenital The anterior part of the upper lobe is consolidated by a catarrhal pneumonia and the bronchi contain a quantity of purulent mucus which appears in large drops on the cut surface when the tissue is compressed The left lung is comparatively healthy and a portion of the lower lobe when thrown into water floats readily The heart presents very healthy characters *Abdomen* —The liver is somewhat congested but is otherwise healthy The gall bladder contains fluid bile The spleen is somewhat congested The stomach appears quite healthy as are also the kidneys

I had intended that the lungs in this case should also have been subjected to microscopic examination and had given instructions to this effect, but unfortunately the organs were lost in the pathological department. Mr D McCrorie's bacteriological report I will read to you a little further on

CASE 3 —The patient, aged one year and 10 months, was admitted to Ward 8 on Dec 12th, 1901, and died the next day The child had suffered from measles about two months before admission and since this illness she had never regained strength About a fortnight before entering the ward she began to cough and to be very drowsy and by Dec 6th she was obviously very ill On the evening of that day the cough was very severe and hard and the breathing was very rapid She refused food but was very thirsty Her skin was very hot and remained so until the 10th, but since that date the mother thought it had not been quite so feverish Dr A. Galbraith Faulds saw her on Dec 8th and diagnosed pneumonia. On the 12th he saw her again and sent her to the infirmary The father and mother were healthy , of five children three survived , one had died from inflammation of the lungs after a week's illness and the other from convulsions following measles The condition of the child on entering the ward was very critical. Dr Scott's note informed us that the face was greatly cyanosed , that the respirations were very rapid, numbering 103 per minute , and that cough occurred in frequent severe paroxysms, followed by some white frothy mucus that had to be wiped from the mouth after the seizure The temperature was 100 4° F and the pulse was so rapid that it could not be counted No dulness was anywhere detected, but over the whole chest fine crepitant râles, chiefly with inspiration, could be heard , the râles were more abundant and of coarser quality at the left apex in front and at the right base behind The heart's action was very feeble and no precise note of its condition was possible The abdomen was not much distended, the spleen was not palpable, and the hepatic area was not increased. On the morning of the 13th I saw the patient at our ward visit and if I read to you the note which I then dictated it will indicate to you sufficiently the further course of the case.

The child this morning is critically ill and lies in bed without noticing much and without much resistance to being handled The breathing is exceedingly rapid and the expirations are laboured and panting There is very vigorous action of the alæ nasi The complexion is very pale but after a fit of coughing there is considerable lividity The temperature has been gradually rising from 102° F at 8 P M last night to 103° at 8 A M this morning No dulness can be detected at any part of the surface of the chest but at the right base behind and at the right apex in front numerous fine liquid râles, chiefly on inspiration, are detected All the phenomena indicate a severe acute capillary bronchitis or broncho-pneumonia.

Such was my note of the condition on the morning of Dec 13th. The child died on the night of the same day at 11.15 At 8 P M the temperature was 105°, and at 11 P M it was 106° Two convulsions occurred at 5 P.M and 8 P M , in which on the whole the left side of the body was more involved During residence the bowels were loose, having been moved seven times The following are the blood counts as taken by Dr Scott. The fresh specimens showed little tendency to rouleaux formation and there was very great leucocytosis Dec 12th hæmoglobin, 90 per cent. , 11 A M , red blood corpuscles, 4,800,000, and white blood corpuscles, 236,000 Dec 13th hæmoglobin, 60 per cent. , 11 A.M white blood corpuscles, 227,810 Differential count polymorphonuclear leucocytes, 33 6 per cent. , lymphocytes, 50 2 per cent., large mononuclear, 15 2 per cent. , and eosinophiles, 0 57 per cent. There was no post-mortem examination

NOMENCLATURE.

Three names, as I have stated at the beginning of this lecture, are indifferently applied to the acute pulmonary disorder of children at present under consideration the names are "acute lobular pneumonia," "acute broncho-pneumonia," and "acute capillary bronchitis " Such a terminology, applied to what is generally regarded as an independent disease, indicates a considerable divergence of opinion as to its clinical history and its pathological anatomy, and it must be admitted that there are prominent features in the symptomatology and the morbid anatomy of the disease which could be adduced in support of each or all of the terms especially of the first two At the same time it is not to be doubted that the disease would be better designated if that were possible by one term than by several. I do not know whether such a simplification of nomenclature can at present be accomplished but perhaps a few critical remarks may indicate the direction in which such a satisfactory result might be attained. If the term acute lobular pneumonia could be abolished I think it would tend towards the simplification which I desiderate The name infers a relationship between acute lobar pneumonia and the disease we are considering which I believe does not exist either clinically or anatomically Perhaps the use of the word pneumonia" in the name is more to blame for this erroneous conception of the relationship of the two diseases than the term lobular That the pulmonary consolidations in acute broncho-pneumonia are multiple scattered and usually of moderate size justifies the use 'of the term lobular' but neither the macroscopic nor the microscopic nature of the consolidated areas indicates that they in any way are related to the lesion of acute lobar pneumonia. Hence I am of opinion that the term lobular pneumonia should not be used.

As regards the name broncho-pneumonia, the same objection applies to the use of the word pneumonia. The pulmonary lesion in acute lobar pneumonia is a fairly constant one, limited to certain definite histological elements as a rule, and generally as definite in its development as is the clinical course of the disease itself Such constancy of structural development is not present in acute infantile broncho-pneumonia. As I shall shortly point out to you in two of our cases we have had to deal with a generalised inflammatory lesion of the respiratory apparatus involving all the histological elements, the bronchioles, the alveoli, the interstitial connective tissue, the pleura, and even the adjoining serous sacs. The lesion presents the anatomical characters of a simple rather than of a specific inflammation of the lung whereas, as I have elsewhere tried to show the word specific fitly describes the anatomical characters of the lesion in acute lobar pneumonia.[1]

The name 'capillary bronchitis is correct in so far as it indicates the serious involvement of the bronchioles But I do not think that it is satisfactory because it does not sharply enough distinguish the disease which we are considering from ordinary bronchitis and it gives no indication of the involvement of the other elements of the pulmonary tissue. Besides, it implies the opinion that the disease necessarily begins in the bronchial tubes, and while I am not prepared to say that it does not I think that there is at least a fair probability that in some cases the infection may be carried by the arteries

These are the critical remarks which I desire to make as to the nomenclature of this interesting and far too common and fatal disease of infancy I have not arrived at these views hurriedly During my whole career of 15 years as a practical pathologist my attention was constantly being directed to the matter and in 1899 on the invitation of the Glasgow Southern Medical Society I formulated my views as a contribution to a discussion on the subject. On that occasion I was not so clear as I am now on the misleading tendency of the word pneumonia as applied to the disease which we are considering and while I am well aware of the danger of attempting to upset a fairly settled nomenclature I would venture to suggest that the term acute infantile broncho-pneumonitis" would designate all the phenomena involved more correctly than either of the three names I have been discussing

ETIOLOGY

The acute broncho-pneumonitis of infancy may be classified as primary and secondary As Goodhart points out, the primary form is more liable to occur in infants beyond the age of infancy the disease is more likely to be secondary[2] The truth of this statement is supported by our first two cases, in which the patients were aged respectively nine and 15 months and in which the disease was apparently primary in the third patient, aged one year and 10 months the disease was secondary to measles. Among the exciting causes of the primary form chill from exposure to cold is certainly one of the most powerful It may cause the disease in quite healthy infants, but is perhaps more likely to do so in those who are weakly or have been suffering from a bronchial cold or from gastro-intestinal catarrh The association of acute broncho-pneumonitis in infants with acute gastro-intestinal catarrh and diarrhœa is a circumstance which has been frequently insisted upon by writers on the diseases of children. In the first and third of our cases there was marked looseness of the bowels under observation in the ward and in one of them green diarrhœa" at a previous date had been very troublesome In the first case the post-mortem examination revealed catarrh of the stomach and intestines and congestion of the Peyer's patches. In the second case the gastric mucous membrane was reported to be healthy and there had been no evidence during life of gastro-intestinal catarrh. Catarrh of the stomach and bowels must therefore be regarded as a powerful predisposing cause or a frequent associated condition, unless indeed the intestinal disorder is itself brought about by the same influences which cause the acute broncho-pneumonitis.

Of secondary acute broncho-pneumonitis whooping-cough measles, and diphtheria are probably the most frequent antecedent states and on the whole such secondary cases are perhaps properly to be regarded as complications or sequelæ. Perhaps too, such forms of broncho-pneumonitis are more likely to be subacute or chronic in their course than the primary forms and many of them terminate in tuberculous conditions.

This is all that need at present be said as to the clinical aspects of the etiology as to the infective agent we must appeal to the bacteriologist.

BACTERIOLOGY

Mr McCrorie, bacteriologist to the infirmary made cultures from the organs of the two cases in which post-mortem examinations were made and reported as follows —

Case 1 —The spleen yielded a pure culture of Fraenkel's pneumococcus. The inflammatory exudation from the inflamed pleura and pericardium yielded cultures of pneumococci and bacillus coli communis. *Case 2* —Cultures from the pleural exudation yielded no growth The spleen gave pure cultures of the pneumococcus of Fraenkel. Pus from the bronchial tubes contained the pneumococcus and tubercle bacilli

Two observations do not count for much in a complicated question such as that now before us but it is worthy of note that in both cases the pneumococcus of Fraenkel was obtained by a skilled bacteriologist. The presence of the bacillus coli communis was so unusual that Mr McCrorie was inclined to think that its presence was perhaps, due to contamination in the course of the necropsy but allowing for such a possibility the presence of the colon bacillus in the pleural and pericardial exudations is at least interesting and suggestive in view of the remarks I have just been making as to the association of acute broncho-pneumonitis and gastro-intestinal catarrh.

According to Ashby and Wright[3] the commonest micro-organism found is the Fraenkel Weichselbaum diplococcus—i.e. Fraenkel's pneumococcus. In the septic pneumonias following measles scarlet fever and diphtheria various organisms are found among others the staphylococcus and streptococcus pyogenes. But, they conclude, it seems exceedingly probable that there are several micro-organisms which if the conditions are favourable, are capable of giving rise to inflammation of the lungs. With this remark I am in perfect agreement, especially as I think that we cannot regard the acute broncho-pneumonitis of infancy as in any sense a specific disease—i.e as one due to a single specific microbe.

I cannot, however leave the discussion of the bacteriology of acute broncho-pneumonitis without directing your attention to a very important paper by Dr Henri Meunier entitled Dix cas de Bronchopneumonies infantiles dues au Bacille de Pfeiffer (Influenza Bacillus)[4] As the result of a long and most carefully controlled bacteriological research Meunier concludes that among the numerous microbic agents capable of infecting the respiratory system in infants we must include the influenza bacillus. In certain cases it would seem to have been the only organism present, at least in the earlier stages, and its presence renders the lungs more liable to the infectious influence of other organisms. The prognosis of influenza cases depends above everything upon this tendency to mixed infection, which must always be carefully guarded against. We have here, then, the demonstration of another important element in the bacterial etiology of acute infantile broncho-pneumonitis and another proof in my opinion that the disease is not caused by one (specific) but by many micro-organisms.

The discovery of tubercle bacilli in the bronchial tubes of the second of our cases is also of the greatest interest in its bearing upon the well known tendency of many cases of acute broncho-pneumonitis to terminate in chronic pulmonary tuberculosis.

MORBID ANATOMY AND HISTOLOGY

Of the naked eye appearances, which were demonstrated to you on the post-mortem table, and the main facts of which have been recorded in Dr Workman's reports, the most striking feature was that the inflammatory lesion was not confined to one part of the respiratory apparatus. The inflammatory change was not limited to the bronchial tubes, as in simple bronchitis, or to the pulmonary alveoli and pleura, as in acute lobar pneumonia. In both of our cases the inflammatory process had almost equally invaded all the structures of the lungs, the tubes, the peri bronchial tissue, the alveoli, the interstitial tissue, and the pleural membrane. In one of them it had likewise spread to the pericardium. As to the minuter details of the naked eye appearances I need not further direct your attention—this is rather the duty of my colleague Dr Workman in his demonstrations on morbid anatomy—but for the sake of my argument I am anxious to insist upon the universal character of the inflammatory lesion and thereby to impress upon you what I think the bacteriology of the disease also indicates—the fact that in acute infantile broncho-pneumonitis we are dealing with a simple rather than a specific inflammation of the lung.

Under the microscopes on the tables I have placed for your inspection a series of sections from Case 1 prepared by Dr Walter K Hunter, my *chef de clinique*, and these sections will also, I think, clearly demonstrate to you the widespread character of the inflammatory process. The sections have been made from the consolidated apex and the base of the right lung and from the "small areas of collapse" in the left lung. Under one microscope a bronchiole has been placed. You will observe that its epithelium has desquamated and blocked the tube. The submucous tissue is infiltrated with leucocytes and round about there is a most intense peri bronchitis. A second microscope shows the condition of the pulmonary tissue in the neighbourhood of such a bronchus, and this can only be described as a very acute interstitial pneumonitis. These are the characters of the central parts of the consolidated areas. Under a third microscope you will see the marginal parts of the consolidated area, here, in addition to the interstitial changes, you will observe a catarrhal proliferation going on in the alveoli, although nowhere is this a very marked feature. A fourth microscope shows the consolidated apex of the right lung. Here almost all trace of pulmonary tissue is lost in the intense proliferation of leucocytes and connective tissue corpuscles that has occurred, so that at some points we have almost the appearances of abscess formation. Under a fifth microscope you will see that the "small areas of collapse" in the left lung are in reality small areas of interstitial pneumonitis, lying immediately beneath the pleura and in immediate association with blocked bronchioles. The last microscope shows the intense fibrinous pleuritis at the base of the right lung. In fact, the microscopes demonstrate a most intense inflammatory process involving all the structures of the lungs, and justify the use of the name "broncho-pneumonitis" in the sense I have already suggested. I have no doubt that had it been possible, as I fully intended, to have made a microscopic investigation of the parts in the second case very similar histological changes would have been discovered.

HÆMATOLOGY

In all the cases the blood was examined, and in each several differential counts of the blood corpuscles were made by my resident assistant, Dr Scott. The details of these examinations I have already read to you, and I now merely desire to point out that in all the cases a leucocytosis was demonstrated. In the first two cases the leucocytosis was not great but was quite distinct. In the third case the number of leucocytes was so excessive as to excite special attention. So careful was Dr Scott to avoid error in this case that he asked one of his colleagues, Dr R. Ramsey, who has also had special experience in blood examinations, to make an independent examination. Dr Ramsey arrived at the same result as Dr Scott, indeed, he made the number of leucocytes somewhat greater. In addition to their excessive number Dr Hunter pointed out to me that some of the leucocytes presented peculiarities in their staining reactions on being examined in blood films, but into this aspect of the case I need not enter. What the significance of this very intense leucocytosis in the third case may be I am quite unable to say, but the fact was so remarkable that I showed the blood films at a recent meeting of the Glasgow Medico Chirurgical Society, without, however, eliciting any further information as to its import. For our present purpose, however, the fact of a leucocytosis being present in all three cases is the important clinical fact, especially as all the cases terminated fatally. It is believed by some observers that a leucocytosis, especially if at all marked, is of favourable import as regards prognosis, but our present observations do not confirm this opinion.

SYMPTOMATOLOGY, DIAGNOSIS, AND COMPLICATIONS

It is unnecessary that I should dwell very long upon this aspect of our subject. The clinical features and the physical signs are well known and have perhaps been sufficiently described in the clinical reports which I read to you at the beginning of the lecture. One or two general remarks upon the symptoms and diagnosis, however, will form a fitting conclusion to the present exposition. Acute infantile broncho pneumonitis is usually sudden in its onset. The infant may have been weakly or suffering from a bronchial catarrh or a cold in the head, but when the more serious disease begins the symptoms at once assume a more urgent and grave character. High fever sets in and the child soon becomes prostrate. The change in the breathing is very striking, the respirations being very rapid and laboured, and the alæ nasi dilating actively with every inspiration. The cough may not be very urgent, sometimes it is suppressed, sometimes frequent, but generally not very vigorous or paroxysmal. Very often coincidently with the onset of generalised pulmonary inflammation there is disturbance of the function of the bowels, usually showing itself by diarrhœa, occasionally by constipation and tympanitic distension of the abdomen. Marked cyanosis or pale lividity soon sets in and the little patient is either listless and drowsy or languidly restless. The physical signs are often rather indefinite and, on the whole it must be admitted that the general condition of the baby to which I have just been referring is not infrequently of more value in the diagnosis of acute infantile broncho-pneumonitis than the signs made out on examination of the chest. There may or may not be generalised bronchial wheezing, but what does catch the ear on auscultation is the sound of sticky, medium, or fine crackling or subcrepitant râles on inspiration, which though fairly generally distributed tend to linger more persistently in particular areas of the lungs. Sometimes small patches of dulness are detected at various points, some of which may be of such extent as to suggest a lobar pneumonia or a pleural effusion. There may, however, be no dulness at all. The state of the infant is, as a rule, critical from the first and the prognosis is almost always grave.

As regards diagnosis probably the chief diseases from which we must distinguish acute infantile broncho pneumonitis are acute bronchitis, acute lobar pneumonia, and acute pleural effusion. In acute bronchitis the child is generally not so ill, the expression not so languid, the cough is more forcible and paroxysmal, the râles both dry and moist are of a more bronchial type, and there are no areas of dulness. Acute lobar pneumonia may be very difficult to distinguish but may be recognised if the signs on percussion and *auscultation are definitely limited to one* lobe of the lung. Often however it will only be at the crisis, which occurs about the seventh day, that we can be sure of our diagnosis. The prognosis of acute lobar pneumonia in an infant is probably more favourable than that of acute broncho-pneumonitis. In cases of acute broncho pneumonitis, where the areas of dulness are large and situated at the base, it may be very difficult to be sure that we are not dealing with a pleural effusion. It may be necessary to use the exploring needle, and even that may not suffice if the exudation be solid and fibrinous, as in our second case. But perhaps the precise distinction does not matter very much in the earlier stages, especially if I am right in supposing that a pleural inflammation of a severe kind may simply be part of the general pneumonitis as I certainly think it was in our first two cases

One of the chief complications of acute infantile bronchopneumonitis is empyema, though manifestly its presence implies that the child has to some extent rallied or even recovered from the earlier stages of the initial disorder It is quite clear to me that in both of our cases had the children lived a few days longer the thick fibrinous masses in the pleural cavities would have been converted into pus. Empyema should always be suspected if the febrile symptoms show no tendency to abate after a week or 10 days, if dulness persists over a single spot, and if with some alleviation of the more severe general symptoms an irregularly remittent type of fever sets in accompanied by sweating When pus has formed and has been found in the pleural cavity the case should be dealt with surgically at once and usually such cases do well. Another complication of acute broncho-pneumonitis is chronic pulmonary tuberculosis, but this only requires to be mentioned. Occasionally symptoms of acute meningitis manifest themselves towards the end, and sometimes, as in acute lobar pneumonia, death occurs with a temperature steadily rising into the region of hyperpyrexia, as in our third case.

TREATMENT

I shall conclude this already too long lecture by making some very brief remarks upon the general principles which should guide our treatment of acute infantile bronchopneumonitis.

Not the least important point in the treatment is the prophylaxis. It is to be remembered that every common cold or bronchial catarrh or gastro-intestinal disorder in a young infant may pass into the exceedingly severe and fatal disease of which I have been speaking It is obvious, then that everything should be done to prevent such an occurrence No indisposition of the kind I have indicated in an infant should be regarded lightly and the child should be carefully treated and not lost sight of till all symptoms of these initial disorders have passed away In particular the mother should be warned of the danger of exposing the child to cold and of the necessity of keeping him or her warmly though not heavily or tightly clad and gastro-intestinal derangements should be corrected by careful directions as to diet.

In the presence of the acute disorder itself the most important point to bear in mind is the fact that we are dealing with an acute generalised inflammatory disease of the respiratory apparatus the immediate tendency of which is to produce great exhaustion of the vital powers. The disease is very essentially one of debility and treatment should aim at maintaining nutrition and stimulating the failing heart. All measures tending to depress the child should be strictly avoided and for this reason emetics are not to be used. Place the child in an airy room well warmed and if it can be easily managed let the air near his bed be moistened by the steam from a bronchitis kettle. You will find that this will often have a marked effect in soothing the cough Do not load him with clothes but keep him warm and avoid compression of the chest and abdomen by flannel binders. Two or three plain linseed poultices in the course of the 24 hours applied back and front and not too hot are often of service as mild counter-irritants Feed the child by milk diluted or peptonised and check diarrhœa by subnitrate of bismuth, combined if necessary with one or two grains of Dover's powder Alcoholic stimulants are almost always necessary but they should be strictly supervised by the medical practitioner ordered by him as occasion demands and prescribed as Sturges[4] recommends—in minims not in drachms. A mixture containing from half a grain to a grain of carbonate of ammonia and two minims of tincture of digitalis in each dose, made up with syrup, may be given every three or four hours. The child should be constantly watched by a competent nurse and should occasionally be held up to relieve breathing

These, it seems to me, are the general principles which should guide our treatment of this very fatal disease of infancy

---

OCCLUSION OF THE LATERAL SINUS AND INTERNAL JUGULAR VEIN AN ESSENTIAL PART OF THE METHOD EMPLOYED BY NATURE, AND BY THE SURGEON IN IMITATION OF NATURE, FOR ARREST OF ACUTE GENERAL INFECTION HAVING ITS ORIGIN WITHIN THE TEMPORAL BONE[1]

BY CHARLES A. BALLANCE, M S. LOND,
F R.C S ENG

SENIOR ASSISTANT SURGEON TO ST THOMAS'S HOSPITAL AND LECTURER ON SURGERY IN THE MEDICAL SCHOOL; SURGEON TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, AND TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET

IT has been said of the speech of Burns that it was distinguished by always having something in it and that always when he did speak it was to throw new light upon the matter I know not, adds Carlyle why anyone should ever speak otherwise.'[2] When I received an invitation from your secretaries to open a discussion on the surgical principles which should be our guide in the operative treatment of an acute septic process arising in the temporal bone, with special reference to the question of operation on the vena jugularis interna, these words came into my mind and I asked myself how I could best conform to their standard. In presenting to you the fruit of personal observation and reflection I hope at least to avoid matter needless of importless burden[3] for men will listen to any Sermon or Sermo when it *is* a spoken Word meaning a Thing and not a Babblement meaning No-thing[4]

There can be no question that there is a wide divergence of opinion on the subject before us. This was impressed upon me during a flying visit which I made last summer in the pleasant and instructive company of Dr Barkan of San Francisco, to the otological clinics of Körner Lucae, Trautmann Jansen Schwartze and Grunert, Barth Politzer and Bezold. In one clinic the vein was always tied, in another it was never tied in a third it was not dealt with unless symptoms persisted after the temporal bone operation had been carried out, and in yet a fourth it was strongly urged that the lateral sinus and internal jugular vein should be slit open for the whole extent occupied by infected clot even should this mean an operation extending from the torcular to the subclavian. No one I think, will contradict the statement that in Great Britain a like divergence of opinion prevails.

'Tis with our judgments as our watches none
Go just alike yet each believes his own "[5]

There are few of us, I take it who have not been present at an operation during which the question has earnestly been asked Shall I tie the jugular?

"Heaven from all creatures hides the book of Fate.[6]

And the surgeon—

His wit all see-saw between that and this "[7]
Hangs between in doubt to act or rest "[8]

and trembles lest the momentous choice which is required of him may end or mend[9] the life of his patient. I not less than each of you have felt the pressure of this responsibility and conceive it to be your wish that the position should be frankly stated and so,

Without offence or with to friends or foes,
I sketch your world exactly as it goes.[10]

Differences of practice in matters of detail are advantageous and tend to progress, but chaotic views as to the bearing of surgical principles must lead to disaster and to death.

Want of agreement among serious surgical workers in a grave question of surgical treatment arises either from the lumping together of clinical conditions having an essentially different pathological basis or from the essential pathological conditions being not clearly understood All true and lasting surgical practice is based upon pathology and when once the pathology of an affection is clearly appreciated divergence of view as to its treatment ought to disappear

Where is now the discussion as to the indications for operation in strangulated hernia, ovarian tumour, or even appendicitis? The operation now before us has for its object the prevention or the arrest of acute septicæmia or acute pyæmia occurring as a further consequence of septic processes which have already begun in the temporal bone. The principle upon which the operation is based—namely, the occlusion of the main venous channel leading from an infected area—is not simply one of local application to the temporal bone It would be good practice, for example, to obstruct the deep femoral vein in septicæmia having its origin in acute necrosis of the femur

In this paper I propose to discuss, not details of cases, but fundamental principles, and it therefore appears to me to be of the first importance to survey the position from the widest standpoint of surgical knowledge and practice

The Universal Cause
Acts, not by partial, but by general laws [11]

And

"Of all the causes which conspire to blind
Man s erring judgment and misguide the mind [12]

there is none so common amongst us mortals as that lack of judgment that

'Still makes the *whole* depend upon a *part*" [13]

The surgeon's

very eyes
Are sometimes like his judgments blind [14]

for

something sure
Hath puddled his clear spirit and in such cases
Men s natures wrangle with inferior things
Though great ones are their object ' [15]

Septicæmia and pyæmia, which arise from infection of parts of the body other than the temporal bone, may present various clinical varieties (1) a fulminating general process without active inflammation at the seat of inoculation, as in acute septicæmia resulting from a puncture made at a post mortem examination without the occurrence of abscess in the finger which was pricked, (2) a fulminating general process with signs of inflammation at the seat of inoculation, (3) cellulitis rapidly spreading from the site of local inoculation with signs of violent general infection, as in acute traumatic gangrene, (4) acute local suppuration in bone with septic thrombosis of the venules, the infection being carried from these into the general circulation, as in acute osteomyelitis, and (5) infection from without of a local chronic suppuration, the pus putrefying and causing subsequent general infection, as in the cases of necrosis after amputation so commonly seen before the antiseptic era

SOME REMARKS ON VENOUS INFECTION

When the general infection is very acute it seems that the circulation must be primarily involved in the infection.[16] A clear statement of this important pathological fact was made by the ghost of a fatal case of aural septicæmia —

"And in the porches of mine ears did pour
The leperous distilment whose effect
Holds such an enmity with blood of man
That swift as quicksilver it courses through
The natural gates and alleys of the body
And with a sudden vigour it doth possess
And curd,
The thin and wholesome blood [17]

Why is general infection uncommon from a finger prick? Because the infective particles do not find a ready way into the general circulation but are dealt with by the cellular tissue. In slight wounds capillaries rather than venules are punctured Moreover, the superficial veins of the limbs run a long course before joining the large deep veins, and their valves are sites at which septic matter is not seldom arrested Why is general infection so common a result of septic infection of the uterus after child birth? Because there is a ready way into veins of large calibre, with but little protective cellular tissue intervening An illustration of the disastrous effects of sudden access of septic material to the general circulation is afforded by the violent septicæmia which occasionally follows operations involving the opening up of old and septic sinuses Again, unless the local anatomical conditions are specially favourable to the infection gaining the interior of a large vein, infected blood from a local infective area is largely diluted with pure blood before reaching the heart. Even with large collections of pus, as in empyema, unless the pus becomes putrid a considerable time usually elapses before the patient is seriously threatened with general infection. Varying virulence of the infection can only be judged of by its effects Independently of the nature of the micro-organism the manner of inoculation may influence the result. "Sinus phlebitis is most frequent in streptococcus otitis All infective agents which may give rise to otitis may on occasion cause a pyæmia spreading therefrom, but are only exceptionally observed in proportion to streptococci." [18]

The distinction of septic infection from septic intoxication is not often required, it is important, however, to bear it in mind. A few years ago I published a case of lateral sinus sapræmia which bears this out.[19] Brieger refers to cases of toxæmia and goes on to say "Eulenstein saw such a case of acute pyæmia in which metastases were absent, caused by mural sinus thrombosis, continued fever of several days' duration was alone present with sudden death in collapse, apparently a purely toxic effect." [20]

Free circulation of the infective agents in the blood stream is the essential condition of general infection This may be a primary result of the initial inoculation or may occur secondarily after local effects have been produced. The explanation of these differences is not clear A quite similar phenomenon occurs in certain of the acute specific fevers

In acute general infection coagulation of the blood in a large venous channel is not a common occurrence It is indeed accidental in the sense that its occurrence depends, as a rule, on the spread of inflammation from the primary source of infection to the wall of the great venous channel. In acute suppuration surrounding a large vein the vein is seldom affected, tension of pus and direct entry of small veins into the large vessel being absent, and the lymphatic sheath barring the infection of the venous wall For example, the internal jugular vein does not usually become thrombosed as a result of angina Ludovici. The conditions are the exact opposite in suppuration surrounding the lateral sinus, the pus is under great tension, there is abundant opportunity for small infection, and there is no lymphatic sheath In osseous tissue generally direct venous infection is more likely to occur than in soft tissue, but nowhere do veins from bone enter a large venous channel after a shorter course than in the temporal bone, and this, I think, constitutes a special source of danger

From much that has been written on the subject it might be thought that thrombosis of the lateral sinus or jugular vein is a necessary step in the development of septicæmia or pyæmia from temporal bone disease This is not so, the occurrence of thrombosis is here an accidental phenomenon due to the peculiar anatomical relation of the lateral sinus and the jugular bulb to the temporal bone, which has no exact counterpart in the rest of the body The lateral sinus being situated in a groove in the bone itself, in close proximity to, and in intimate connexion with, the diseased area, becomes involved in the local septic process and thrombosis results. The sinus thrombosis is really a *protective measure* and when the clot remains uninfected it is successful.[21] The thrombus, however, may become infected and the disease will then

'Break out into a second course of mischief" [22]

[22] Henry V, Act IV, Scene 3.

Thus is set up an additional source of danger often of such gravity that it overshadows the primary disease.

Thrombosis occurring in a great venous channel like the sinus does not lead to its sudden occlusion. The clot which first forms in the vessel as the result of an alteration in its lining membrane lies along the wall of the vessel but does not occlude its lumen. By the addition of successive layers the clot may extend so as completely to arrest the stream of blood through the vessel. Blocking of the channel may however not occur in consequence of the cessation of the clotting process, or the block may fail to be permanent by reason of the contraction of the clot. From the close proximity to and intimate connexion of the vessel with, the infective area in the bone infection of the clot occurs, so that there comes to be an additional local centre of infection continuous with the primary one, from which not only micro-organisms but gross particles of infective clot may be carried into the circulating blood. Then there is present that most dangerous condition—an infective thrombus with a but partially obstructed blood current. It is here that the surgeon may happily complete what nature has failed to carry through. In the rare cases in which septicæmia or pyæmia occurs from temporal bone disease without obvious infection or obstruction of the sinus or vein the infection has been so virulent that no local protective thrombosis has even been attempted. It is the secondary infection of the clot and *not the occurrence of thrombosis* that constitutes the danger

Brieger appreciates the fact that thrombosis is an epiphenomenon. He says Such metastases without the intermediary of venous thrombosis occur in mucous membrane affections analogous to middle-ear suppurations. Such are the secondary manifestations of gonorrhœa which may be described as gonococcus pyæmia. The occurrence of this form of pyæmia without sinus thrombosis by means of purely bacterial emboli rendered probable by clinical observation is becoming unequivocally demonstrated by anatomical observations. It is especially in pneumococcus otitis that general infection of this nature occurs. [23] On rare occasions the blood may so teem with microbes that when clotting occurs in the sinus the thrombus may from the first be infected.

When thrombosis takes place in a large vein from the milder septic infections of the cervix uteri, though the local effects of the blocking of the venous channel are troublesome enough, there is not commonly breaking down of the clot and pyæmia, because the conditions leading to the secondary infection of the clot are for the most part wanting

Jansen[24] explains some rare forms of rapidly fatal general septic infection by referring the path of infection to the lymphatics. If this were so it would really be *venous infection* at *another point* but the narrow calibre of the lymphatics and the intervention of glands along their course render it difficult to understand how general acute infection can occur by way of the lymphatic system without intermediate local effects. In these cases a local gangrenous process of bone and soft parts sets in,[25] putrid pus exudes, and the surface presents a greenish grey appearance The examination of the bulb of the jugular has not always been made with such care as is needed to detect small circumscribed diseased spots in parts of the vessel wall which are only with difficulty accessible. In the cases of acute sepsis which I have observed I have found," says Jansen, thrombo-phlebitis of the jugular in which the septic thrombus was not shut off by firm uninfected thrombus. In this particular form of septic illness such (thrombotic) processes, or only mural thrombi, alone come in question and not the common form of occlusive thrombo-phlebitis. The observations found in literature are not all beyond doubt. Whether or how the bulb of the jugular was examined is mostly not apparent. So there still drags the decision of the question as to how far this particular clinical type of disease really occurs without the intermediary of involvement of the sinus or jugular vein "[26] By the pressure of an extradural abscess the sinus may be obstructed and the development of a thrombus brought about in a purely mechanical manner [as by an aseptic ligature which causes coagulation by inducing a proliferation of the endothelium] without any infection and without the possibility of a secondary pyæmia. The outer wall of the sinus is thin, being only the thin outer layer of the dura. The septic infective process much more readily spreads through this thin wall and reacts upon the endothelium and sinus contents than through the whole thickness of the dura. The immediate effect of an extra dural abscess is for the most part confined to the outer layer of the dura, the sinus is thrombosed, but the brain is found still covered by the intact inner layer of the dura. The thrombosis which is caused by compression of the sinus in a purely mechanical manner may when the focus of infection has been removed remain uninfected To attack such a thrombus by operation would be an error Even contact with the needle used for paracentesis [a futile procedure in any circumstances] might infect it. The earlier pyæmia arises in acute ear infections the more probable is it that the point of departure of the general infective process is to be sought in the bulb."[27]

The small mural thrombi alleged so often to have been overlooked in the bulb are not necessarily the cause of the pyæmia. They may in some cases represent an *abortive attempt at protective occlusion*. Too much stress has been laid on the lateral sinus and the jugular bulb as the sole seat of infective thrombosis. I have had a case of pyæmia due to superior petrosal sinus infective thrombosis, without thrombosis of the lateral sinus. This point is touched upon in certain of the text-books[28] and by Jansen.[29] Brieger[30] says Primary thrombi arise in the superior petrosal sinus, especially from suppuration in the labyrinth, and are also observed in acute suppuration in the tympanum in scarlet fever" The size of the lateral sinus concentrates the mind too exclusively upon it, while in pyæmia resulting from disease in other regions of the body no large vein being in near proximity to the disease, the attention is not distracted from the numerous small veins, each one of which may harbour an infective thrombus which may equally produce the disease.

The process of disease in the temporal bone and in the tissues around it is one *continuous* infective process. It is a mistake to think of the infection of the osseous, dural and blood tissues as separate pathological entities. The differences are anatomical and physiological not pathological. As the spread of the infection is by continuity of tissue the infection of the dura, for obvious anatomical reasons, precedes that of the blood The march of the infection will thus be in this order perisinusitis, sinusitis, blood infection. Infection of the blood suddenly brings into being a new factor for it is infection of a tissue the liquid texture of which confers upon it the physiological property of constantly travelling through all the tissues of the body

SOME SURGICAL AND PATHOLOGICAL REMARKS.

Nature s process for the prevention of general infection is sequestration of the infective material as is shown by the formation of local abscess. Thus nature surrounds the poisoned tissues, be they in bone, in dura, or in blood (by coagulation), with an inflammatory barrier and the surgeon, as the plan of nature for the saving of life is unfolded before his vision, learns the lesson of how and by what means, surgical art may successfully deal with acute septicæmia and acute pyæmia. These cases have one thing in common—they are always acute. The only subdivisions we can recognise have to do with their early history and are as follow (1) those in which the acute illness follows on and develops from a chronic suppuration, and (2) those in which the acute illness is but a further stage of a recent acute suppuration. But these differences in origin do not justify the notion that the surgical treatment suitable in the one case is not equally right and proper for the other I contend that the principles of surgery apply in either case without modification detraction, or alteration Körner[31] quotes from Schwartze that more than half of the cases of otitic pyæmia get well without ligature of the jugular by simply opening the antrum, with or without clearing out the broken down thrombus in the sinus", and he adds as a comment "Here cases of pyæmia with and without sinus phlebitis are confused together" I cannot but think that there is also confusion in Schwartze's statement between the cases with pyæmia and the cases which though acutely ill, had only a local affection. Just as a patient who has pus pent up beneath the palmar fascia, though he may be acutely ill, is not necessarily suffering from septicæmia or pyæmia, so it is true that a patient with temporal bone suppuration, though acutely ill, may also be the victim of a *local rather than a general process* This is a point upon which the surgeon's mind should be clear before he proceeds to operate. In the temporal bone there may be acute or chronic suppuration spreading from the tympanum and mastoid to the lateral sulcus without obvious thrombosis or severe inflammation of the lateral sinus and jugular vein. In such a case operation on the sinus or vein is not necessary unless there is evidence of general infection "When a periphlebitis has been exposed we are justified in stopping the operation and awaiting the result, if the patient is not already suffering from a severe pyæmia."[32]

[30] Brieger loc. cit., p. 65.

[31] Die Otitischen Erkrankungen des Hirns second edition p 79

Even if suppuration has involved the dura mater and coagulated the blood in the sinus the opening of the local abscess in the groove or in the sinus may cure the case—i e, if nature has provided against general infection by occlusion of the sinus Brieger says "Even a thin layer of a sound clot may be an efficient barrier against embolic detachment of particles If the apparently healthy terminal portions of clot are allowed to remain suppuration may, however, occasionally arise therefrom. As I have demonstrated, not every apparently sound terminal portion of clot is really poor in bacteria The subsequent breaking down of these terminal portions has, however, scarcely any danger provided that there is such a free opening as to ensure the ready escape of the products of suppuration." [The danger is diminished if there is a free opening, but is it true that it scarcely exists? Do we in these cases obtain an opening which is surgically free? The danger would surely be much less if the jugular were tied.] "Certainly, if we restrict ourselves to the removal of the pus or the breaking down clot we may overlook a spreading 'disconnected' thrombus on the far side of the sound portion Against this the most complete clearing out of the sinus will not protect us."[33]

The sinus and vein constitute the main route by which the infective agents travel, whether thrombosis has occurred or not. If nature has placed an effectual block in the shape of an uninfected thrombus on the cardiac side of the infective focus the surgeon has been anticipated in the most efficient and effectual manner But as Viereck[34] remarks "Surely we should not rest content with the always doubtful evidence of occlusion which an apparently sound thrombus affords if we considered ligature (of the jugular) as entirely free from danger" It cannot, then, be true that in a given case there are indications and contra indications for operation on the vein

> Nature and wisdom never are at strife "[35]

The question is as to the *exact diagnosis*, not as to the right method of treatment, for in a particular morbid condition there are not two right plans of treatment but one right plan of treatment Yet in actual practice—

> So vast is Art, so narrow human wit [36]
>
> The lyfe so short the craft so long to lerne
> Th assay so hard so sharp the conquering [37]

there may be doubt as to the exact pathological condition present and then vacillation as to the course to be pursued may arise. From the experience, often dearly enough bought, of many workers certain valuable guiding principles of treatment can be with some precision formulated and much of the knowledge which has been gathered can be imparted The divine gift of judgment

> ('For judgment only doth belong to Thee') [38]

is, however, incommunicable, but I demur to the view that the possession of this gift is confined to the select few Pope says

> 'For if we look more closely we shall find
> Most have the seeds of judgment in their mind' [39]

We speak of some animals as being sagacious, and the sagacity of brutes is allied to the talent of instinctive judgment in men. Shakespeare might have written of brutes in a lesser degree, no doubt, what he did of mankind

> "By a Divine instinct men's minds mistrust
> Ensuing dangers as by proof, we see
> The waters swell before a boisterous storm "[40]

An acute observer once said to me of one of Britain's greatest physicians, now deceased, "He was the most sagacious beast I have ever known." It is true that in times of stress and doubt some exhibit clearer insight and greater courage than others In these the talent of judgment has been zealously nurtured The power of seizing the moment for decisive action in the presence of disease which puts a check on the thread of life winnows out the weak from the strong in judgment

> "The wingèd courser, like a gen rous horse,
> Shows most true mettle when you check his course "[41]

No surgeon would mistake a local abscess of the thigh for spreading cellulitis, but the differentiation of the cases under consideration is a more difficult problem In the thigh the whole condition is visible to the eye, but in the temporal bone a correct inference must be made of the state of parts not visible If after the operation on the temporal bone the signs of general infection persist an error of judgment has been committed and the operation has been incomplete It is true that the vein may now be tied and that some such cases have been successful

> 'Fortune brings in some boats that are not steer d' [42]

But less can be expected from the operation on the vein when done as a secondary measure than when carried out as a part of the first operation

> "Omission to do what is necessary
> Seals a commission to a blank of danger [43]

Greig Smith said in reference to the operation for the relief of intestinal obstruction "Let it be either drugs or operation and never that fatal compromise—operation when drugs fail "[44] "Conviction, were it never so excellent, is worthless till it convert itself into conduct."[45] So here let the surgeon be no "hovering temporiser,"[46] but let him make unflinching decision as to whether the case be one calling for operation on the vein as well as on the temporal bone and not adopt that equally fatal compromise, operation on the vein when operation on the temporal bone has proved insufficient

> "Mistrust of good success hath done this deed.
> O hateful error "[47]
>
> "For things bad begun make strong themselves by ill [48]

Such a compromise exhibits a stuttering state of the surgeon's belief in the efficacy of operation on the vein "When Belief waxes uncertain Practice too becomes unsound "[49] Carlyle defines "Belief to be the healthy act of a man's mind." 'We have," he adds, "our mind given to us, not that it may cavil or argue [and this is a splendid lesson to the surgeon face to face with a grave surgical emergency], but that it may see into something, give us a clear belief and understanding about something, whereon we are then to proceed to act."[50]

There may be also a fulminating general infection from the temporal bone quite comparable to the fulminating general infection from a post-mortem wound, when,

> "The life of all the blood is touched corruptibly "[51]

In these cases less can be hoped from operation on the vein or, indeed, from operation of any kind Not much could be expected from tying the axillary vein or amputating the limb in a case of acute septicæmia from a wound of the finger Serumtherapy and dilution of the affected blood with saline solution offer the main chance of recovery

Chronic suppuration of the temporal bone is a more frequent cause of acute general infection than is acute suppuration It has been remarked, and this is in accord with my own experience, that 'pus forming around the sinus seems more readily to induce gangrene of the sinus wall and septic infection of its contents when it has resulted from chronic suppuration in the bone than when it has resulted from acute [52] Thus we have again an acute condition to deal with but here superimposed upon a chronic. The acute symptoms may or may not be associated with coagulation of the lateral sinus blood. The remarks of Körner and Jansen as to the frequency with which clot in the bulb has been overlooked must be borne in mind. Jansen says In a case of severe septicæmia I found the upper part of the jugular vein necrosed as early as the seventh day after the first appearance of the fever and the acute influenza otitis while the sinus was absolutely intact." He adds that 'the phlebitic processes of the bulb present as a whole a graver prognosis as to systemic infection than those of the lateral sinus" and that 'frequently in acute otitis the bulb is in greater peril than the sinus, especially in inflammation of extreme virulence in delayed spontaneous perforation and under favourable anatomical conditions such as protruding jugular fossa with extended apposition of the bulb to the tympanic cavity [53]

In spreading septic thrombosis when the blood of the sinus and vein

Is turned to an infected jelly "[54]

the clot may reach the subclavian or even the heart In this class of case no doubt can arise as to the urgent necessity of *operation on the vein*

Although the danger of infection by way of the blood stream cannot be said to be averted completely unless all the blood from the infected area is arrested (and as ligation of all the veins and lymphatics is impossible this condition cannot be realised by any measure short of complete excision of the whole diseased area, which is, indeed also impracticable) yet as the internal jugular vein is the direct highway along which in these cases highly infected blood is reaching the heart by a short route and with little further admixture with pure blood from uninfected regions, the establishment of a block in the highway must prevent direct access of infective material and so greatly reduce the risk from the primary source.

Experience has shown the great efficacy of the operation on the vein even though the whole of the local disease may not have been removed as in Case 4 of my first paper [55] It is, therefore, idle to maintain that the collateral circulation through the occipital and petrosal sinuses and the condylar and vertebral veins renders abortive the surgical occlusion of the main sinus and vein. These latter represent the wide *gate and broad highway that lead to destruction and when* these are obstructed if the poison finds a new pathway to the general circulation it encounters a narrow gate and a circuitous route which retard its progress and tend to dilute its virulence.

Brieger in a statement qualifying his recommendations for ligature, says It is questionable whether ligature is *needed for the obliteration of the jugular or whether its* obliteration may not be spontaneously brought about just as surely as by ligature through certain processes following sinus-thrombosis. [56] It might just as truly be maintained I think, that operation should be discarded in a case of empyema, since a collection of pus in the chest may be limited by adhesions and discharge spontaneously

It has *sometimes been objected* that the *operation* on the vein is a dangerous procedure and all sorts of bogies such as œdema of the brain and the entrance of air have been conjured up to throw doubt upon the wisdom and advisability of the procedure In general surgery the jugular vein is constantly removed in order to facilitate the ablation of glandular and other tumours of the neck and in my view the operation presents, in skilled hands, no danger and the loss of the vein does not make the slightest difference to the patient "[57] It must be remembered that in most of these cases the operation recommended does not block a still patent venous channel but *one which is already packed* with septic clot and more or less impermeable. The only objection that could be urged against the doctrine of dealing with an apparently uninfected clot in the radical way suggested is that cases not due to ear disease are known in which recovery has taken place after non septic thrombosis of the lateral sinus, and that in these cases canalisation of the clot may occur so as to allow of the passage of blood again along the once plugged sinus. This objection does not appear to me to have *any weight, and the risk* of leaving untreated a clot in the immediate neighbourhood of very virulent septic matter in the hope that it may remain uninfected seems so great that it puts out of court what is at best only an imaginary advantage—viz the chance of the sinus becoming patent again and thus functionally useful to the patient. [58]

STATISTICS AND OBSERVATIONS OF SOME SURGEONS

The appeal to statistics does not have so great weight with me as the matured judgment on the matter in dispute of an experienced surgeon. *This is in part due to the fact that* probably in most of the worst cases the jugular is tied and secondly because in the majority of cases in literature there is no such account as will satisfy a critical examination or will justify a critical personal judgment as to (*a*) the virulence of the disease, (*b*) the local conditions found at the operation and (*c*) the appropriateness of the measures employed by the surgeon. *Nevertheless*, some figures given by Viereck [59] are sufficiently instructive to quote. In 94 cases of uncomplicated thrombosis of the sinus the jugular vein was tied in 40, six died from pyæmia and 34 recovered (85 per cent.), and of these recoveries 28 (70 per cent.) were without complications and six (30 per cent.) were complicated with fever and metastases. Of the 54 cases in which the jugular *was not tied 13 died from pyæmia and 41 (76 per cent)* recovered and of these recoveries 14 only (46 per cent) were without complications and 27 (54 per cent.) were complicated with fever and metastases It therefore appears that ligature prevents metastases. Viereck sums up In ligature [of the jugular] we possess a method which prevents pyæmic infection more surely than does operation on the *sinus alone with which therefore it should always be* combined. In order to avoid the danger of detachment of fragments of clot and of entrance of air into the vein the operation on the vein should precede that on the sinu "

VIERECK'S TABLE

94 Cases of Uncomplicated Thrombosis of the Sinus

—	40 with ligation	54 without ligation
Died from pyæmia	6—i.e. 15 per cent	13—i e., 24 per cent
Cured	34—i e. 85	41—i e 76
Cured without complications.	28—i e 70	14—i e 46 "
Recovered with fever and metastases	6—i e 30	27—i.e 54 "

14 Cases of Thrombosis of the Sinus and of the Internal Jugular Vein

—	12 with ligation.	2 without ligation.
Cured without complications	12	0
With metastases	0	2

Brieger [60] says In the cases of pyæmia in which on account of the negative result of exploration of the sinus, I have believed that mural thrombi were present, I have seen recovery occur without ligature of the jugular although at least one of the cases was characterised by special severity particularly on account of the number and character of the metastases." Ligation, it would appear is most important when the sinus is not completely obstructed by clot.

At the meeting of the German Otological Congress in Breslau in 1901 Jansen, for whose judgment and operative skill I have the highest regard read a very important paper He stated that in pyæmia there was always a diseased sinus, in four only out of his 63 cases had he failed to prove the presence of sinus-thrombosis [61] He recommends ligature of the jugular —1 As the first step of the operation (*a*) in undoubted cases of jugular phlebitis and (*b*) in severe sepsis. 2. After exposure of the sinus (*a*) if the sinus appears sound and there is no perisinous affection, but rigors and marked oscillations of temperature are present, and (*b*) in periphlebitis and mural thrombosis under the same conditions. The sinus should be opened (*a*) on the evidence of the presence of septic broken down thrombus, when the result of puncture is negative, (*b*) in gangrene of the sinus wall, (*c*) in repeated rigors, marked oscillations of temperature, and poor general health, and (*d*) when optic neuritis is present, in most cases if not always 3. After incision of the sinus (*a*) if septic thrombus is, or was, situated in the immediate neighbourhood of the bulb, and (*b*) if after the incision of the sinus the rigors do not cease or the temperature materially decrease or should other cerebral symptoms persist Jansen's table of 50 cases is as follows Of 30 cases without ligation 22, or 73 per cent., of the patients recovered, and of 20 cases with ligation 13, or 65 per cent., of the patients recovered Notwithstanding Jansen's numerous successful cases which recovered without operation on the vein, yet his recommendations for operations on the jugular are so comprehensive that one can scarcely imagine a case of pyæmia which would not come within their scope.

Macewen[62] says "Where the infective thrombus in the sigmoid sinus has undergone such extensive disintegration as is unlikely to be reached by obliteration of the upper two thirds of the sigmoid sinus the ligature of the internal jugular is indicated. When in a thrombosed internal jugular giving the sensation of a hard cord like structure its upper part becomes soft from disintegration of the thrombus, and when this is followed by descending disintegration, ligation of the vessel below this point is in most cases necessary When one can foresee in the outset of the case that the vein requires to be ligatured it had better be done as the first step before clearing out the sigmoid sinus, as greater freedom may then be obtained while performing the latter In the majority of instances the obliteration of the upper two thirds of the sigmoid sinus is all that is necessary for the prevention of systemic infection."

Brieger[63] gives the following figures "Out of the total of 38 *cases* which I have observed 26 were operated on, in 10 the jugular was tied with five recoveries and in 16 it was not tied with eight recoveries, so that the percentage was the same in both series. A critical examination of the individual cases does not materially alter the result—is, perhaps, a little more unfavourable to ligature" The important thing must *be*, not whether a certain number of patients recover without operation on the vein, but whether a certain number of patients die who would have recovered had the operation on the vein been done. Brieger's recommendations respecting the operation are as follow "In my judgment the vein is to be exposed as a preliminary measure only in those cases where the diagnosis of primary bulbar thrombosis is possible with special precision, but after the exposure of the sinus the vein should be exposed in the following cases (1) *straightaway*, in immediate combination with the sinus operation only when the infective process cannot be completely commanded by the operation on the sinus, or does not appear to be, by *this* means, made completely accessible, that is to say—(*a*) if the cardiac end of the breaking down process cannot be reached through the open sinus, (*b*) if when *the sinus* is found normal there exist such local conditions as point, with some degree of certainty, to the presence of jugular thrombosis Further experience must show whether we are justified in endeavouring to determine the *permeability* of the jugular by Whiting's method and by compression of the jugular in the neck, and how far the measures to be adopted should depend on the result of this *investigation.*" [*This method of investigation must be highly dangerous if there is any clot in the vessel.*] "2. During the subsequent course of the case (*a*) if fairly positive signs of the extension of the sinus thrombosis into the vein should arise, (*b*) if with a normal sinus, after the evacuation of perisinous abscesses or other foci from which mural thrombi may *develop, typical* fever and the occurrence of metastases persist In all these cases the exposure is first the important thing, ligature can be combined with it if the nature *of the contents* of the vein allows of the immediate slitting up of the exposed portion Here, again, also, after the exposure of the vessel ligature is to be made dependent upon local indications arising from the inspection of the exposed vein, from the alteration of its degree of distension by compression and from the examination of its contents by exploratory puncture I sum up 1. Sinus phlebitis is always to be treated by operation. The presence even of severe complications or advanced metastases—meningitis, pulmonary abscess with pyopneumothorax—does not exclude the possibility of recovery 2. The operative treatment must always begin at the primary source of infection. The clearing out of this may suffice to bring about the resolution of a pyæmia caused by mural thrombi, and it is in every case indispensable in order to obtain permanent recovery 3 In the presence of unequivocal symptoms of primary thrombosis of the jugular bulb operation is best done on the jugular and not on the sinus 4 Ligature of the jugular cannot entirely prevent the occurrence of metastases and is often unsuccessful when carried out as a purely prophylactic measure 5 It should therefore only be employed upon particular indications"[64] It is worth remark that this summary begins "Sinus phlebitis is always"—it is not the sinus phlebitis which requires operation, on the vein at all events, but the pyæmia

Preysing,[65] in relation to the question of ligature of the jugular, divides the principal forms of sinus phlebitis into three groups (here, again, sinus phlebitis, not sinus-pyæmia) "1. Sinus thrombosis without symptoms—(*a*) quite fresh clot in the sigmoid sinus or (*b*) old occluding thrombi consisting of firm granulation tissue such as are commonly first discovered in the course of a temporal bone operation In both cases ligature should remain undone unless subsequent complications should arise 2 Cases characterised by clear and definite signs of participation of the jugular in the infection or definite pyæmia with metastases Here ligature should always be done and that before the temporal bone operation 3 Thrombi in the sinus softened in the centre but firmly shut off on both sides In these cases ligature should be done if rigors, fever, &c, persist or arise after the temporal bone operation has been carried out, but we can wait with a clear conscience when these threatening indications are absent If ligature must be done in this third group of cases it will naturally follow the mastoid operation, the right may, however, be conceded to every operator, if he believes he has diagnosed this third form of sinus thrombosis, to carry out the ligature before the trephining" This is in practical agreement, when the significance of the last sentence is considered, with the advice I gave when first I wrote on this subject, that operation on the vein should be done when pyæmia is present or is threatened The cases in Preysing's first group are obviously not pyæmia

In the paper, written in 1889,[66] I said "The diagnosis having been made there remains for discussion the question of treatment. This must *in all cases* be two fold—viz., the free exposure and removal of the focus from which pyæmic infection has occurred *or is threatened*, and secondly the establishment of a block in the highway along which the infecting agents are travelling from the local focus into the general circulation. With regard to the vein it should certainly be ligatured *in all cases* of thrombosis of the sinus associated with ear disease, and though it may not be possible to determine whether a given thrombus be septic or not septic, yet the probabilities are so great that if the thrombus be not already infected it will become so, that it would be foolhardy in such a case not to ligature the vein " In the same paper I dealt with the question of pyæmia arising from the temporal bone without obvious infection of the lateral sinus and I wrote "Under such circumstances it behoves us to inquire whether surgical interference offers any hope of life to the patient. The answer to this question is, for me at least, an emphatic affirmative. Whether the sinus be full of clot or moving blood it matters not, in either case the poison is being poured into the sinus, or, say, through the vein of the cochlea into the jugular, and the method which has proved efficacious in saving life in the one case will assuredly if promptly applied be equally successful in the other The local disease of mastoid or petrous must be freely exposed and antisepticised with sublimate solution. The vein must be ligatured in the neck and the sinus must be freely exposed in the usual way behind the ear, opened, and plugged. Thus an artificial thrombosis of the blood

---

[66] Ballance loc. cit

arrested between the plugged sinus and the ligature on the vein will be effected. It will then not be possible for any further infection to happen from the primary source of disease, for the collateral circulation is not sufficient to carry the infective material down the other jugular as is shown by the histories of the four cases on which I have operated. The whole or the greater part of the clot thus artificially induced would not at first be other than healthy in character but it might subsequently become infected with micro-organisms, in which event it would be easy to wash it out, especially if the lower end of the upper segment of the vein had been stitched to the margins of the skin wound in the neck. By these means the surgeon may erect an effectual barrier against further pyæmic infection from the primary focus, which may at once be successful in arresting the symptoms of danger, or may materially assist a patient in combating the symptoms of acute pyæmia until the chronic stage is reached which in this disease is always of hopeful import so far as life is concerned." In a paper written last year for Chipault s international work ' L Etat Actuel de la Chirurgie Nerveuse as yet unpublished, this position is modified by saying Nothing is more striking to those who have had much experience in these cases than the fact that in some the process rests purely local, while in others it rapidly extends in either direction. The pathological conditions being so diverse no absolute rule can be given as to whether or not the internal jugular vein should be tied. The course to be pursued depends upon the condition found. If the suppuration in the vein is localised and the sinus occluded on each side of the area of suppuration, incision of the sinus and drainage suffices for its cure. If, however infected clot is extending along the course of the jugular vein it is as clearly the duty of the surgeon to operate on that vein as it was his duty to operate on the original disease in the temporal bone he must, as we have already said, follow the disease to its utmost limits. That is to say in other words that if when you do the operation the conditions found are such as to make it quite sure that a pure block already exists in the highway you need not make a new one. The principle of the original statement is in no way modified by this concession since nature has then already done what would otherwise be demanded from art. Körner in reference to this question says The cause of the happy result of operations limited to the sinus lies in the fact that the sinus is in most such cases shut off on both sides by solid uninfected thrombi. Again most such cases are instances of early sinus thrombosis unexpectedly found in operating for extra-dural abscess, not yet of great extent and but little broken down. In most cases it cannot be known whether the thrombus has extended into the bulb of the jugular and there broken down from this situation detachment of particles and their entrance into the blood current can take place more easily than from the sinus. The ligature of the jugular is *justified* in all cases of sinus thrombosis and will be *necessary* when the diseased sinus is not firmly occluded on the cardiac side.

The question is more simple if it is known that the thrombus has extended to the bulb of the jugular vein itself Every movement of the head and every manipulation of the neck may cause detachment of particles of clot, and experience teaches us that under these conditions the occurrence of pulmonary metastases is almost constant. All authors are agreed that here the jugular should be tied and that before the sinus is opened."[67] If a considerable flow of ichorous fluid takes places on incision of the sinus," says Jansen,[68] it is to be inferred that the septic breaking down process extends to the bulb, and that the bulb if not already infected, is in immediate danger of becoming so. Under such circumstances the surgeon had best proceed forthwith to the ligature of the jugular" It is impossible, in many a case, to say that there is no reason to fear septic venous infection and in case of doubt operation on the jugular should be performed.

To fear the worst is oft to cure the worst."[69]

CONCLUSIONS

1 *Diagnosis of case before or during operation.*—The surgeon from his examination of the case must, if possible, come to a clear determination as to the condition from which his patient is suffering—whether (*a*) from an acute systemic infection or (*b*) from a systemic disturbance depending upon a local process. When this can be determined beforehand the plan of operation is clear If doubt exists as to the exact nature of the case the matter must be cleared up by careful observation at as early a period as possible during the progress of the operation on the temporal bone.

2. *The operation on the vein*—This should be undertaken (*a*) in acute pyæmia and acute septicæmia, whether the sinus is occupied by clot or by fluid blood (*b*) if the sinus wall is gangrenous or its contents are putrefying unless it is perfectly clear that on both sides of the area of inflammation the lumen of the sinus is completely blocked by non infected thrombi (how seldom this qualification will be operative will be obvious to those who have most experience of these cases) (*c*) if it is proved, or even suspected, that the blood of the jugular bulb is in part or wholly clotted , and (*d*) if the jugular vein is thrombosed.

It will be seen that, in my opinion operation on the vein is called for not only by general systemic infection, but also by certain local conditions. Some observers hold the opinion that the decision of the question as to whether operation on the vein should be carried through depends principally upon the local conditions found, while others think that the decision should depend more upon the state of the patient in general and the febrile conditions in particular The right course to adopt is clearly to give due consideration to all the facts.

When it has been decided to deal with the vein before beginning to operate, the operation on the vein should precede that on the temporal bone, and when operation on the vein is first decided upon during the course of the temporal bone operation it should be forthwith carried through without waiting for the completion of the operation on the sinus region

The vein when not thrombosed is exposed in the neck about the level of the cricoid cartilage, and the surgeon, tying its tributaries and dividing them between two ligatures should remove it completely up to the bulb Ablation of the vein is better than ligature. It involves ligature of the tributary veins and as the line of incision involves the external jugular that vessel is also necessarily tied In cases of thrombosis of the internal jugular the ablation will begin at its junction with the subclavian and it will be no difficult task in these circumstances to find on its inner side, lying on the scalenus anticus, the vertebral vein and to ligate and divide it also.

Lest it may be said that this is too desperate a measure to recommend I would say that in these cases

Strong reasons make strong actions, [70]

and

The only safety lies in the despair of safety "[71]

3 *The completion of the operation on the sinus region.*—Having dealt with the vein the operator returns to the sinus region and removes bone so as to expose the sinus towards the torcular for a distance of at least three-quarters of an inch beyond the area of inflammatory change, and the same treatment is adopted on the other side of the inflamed area, bone being removed in some cases, and probably better in all as far as the bulb, so that the whole area of possible infection of sinus and vein is exposed in one continuous wound

In general surgery an extensive septic suppuration is treated by laying the affected area open by one or several incisions, but in those cases in which it is possible to expose the infected tissues by one incision, however long the best results ensue. If one continuous wound is not made in cases of lateral sinus pyæmia the dangerous area of the bulb is not laid open and the presence here of even small particles of putrefying clot may determine an extension of the infective clot along the inferior petrosal sinus to the cavernous sinus, just as when a ligature has been left on the upper segment of the jugular a test-tube of pus" may form in it and produce a similar disastrous effect. The danger of this practice was pointed out in a previous paper[72]

Jansen[73] says that when he has reason to anticipate further suppuration in the sinus thrombus he exposes the sinus for a greater length so as to be able to extend his incision in it without the necessity for a further bone operation This seems however a recommendation which is not sufficiently thorough going since if further breaking down of the thrombus is likely to happen further incision of sinus is required at the first operation It is impossible to deal with the sinus as with the vein, by removal, as this would expose the intra dural space In acute foul suppuration of other parts of the body we do not curette away the pus and therefore the suggestion frequently found in otological literature, that we should curette away pus or putrefying clot through an opening in the sinus, is one that should be abolished from surgery The obvious proceeding is to slit up the sinus, if necessary from torcular to bulb, so that the whole area of infective inflammation may be exposed and dressed *secundum artem*

[73] Jansen: Encyklopädie der Ohrenheilkunde loc. cit p 371.

Brieger[74] says "No doubt remains as to the measures to be carried out with respect to the sinus The sinus is to be slit up in the whole extent to which it is thrombosed and the tube of the vessel is to be converted into a groove, freely exposed on its outer aspect by the excision of the entire outer wall, and its contents for this portion of its extent completely removed The sharp spoon is not a permissible instrument for use in the sinus because, even when immediate injury is avoided clots may be detached which are serving to shut off from the infected area neighbouring vessels such as the petrosal sinuses, which are as yet intact. *The occurrence of hæmorrhage when clearing out the sinus is* not, *per se*, a proof that the removal of clot is complete By the removal of such portions of clot as block the entrance of the petrosal sinuses sharp bleeding may occur in spite of the lateral sinus or the jugular being full of clot."

4 *Some further considerations* —1 The radical procedure here described will, in certain cases, no doubt commend itself to all, but, as I have already pointed out, it is in the selection of cases that the judgment of the surgeon must come in Want of proper perspective in the selection of the operation suitable to a particular case is well illustrated by the following instance "The two practitioners in attendance had already chiselled away the mastoid a few days after the commencement of the pains in the ear, and that as far as the posterior border of its apex, for they had mistaken the posterior border of the mastoid for the linea temporalis As they had found no pus and as the violent pain persisted and the fever was still higher after the operation in their perplexity they sought my help I incised a boil which completely occluded the meatus, whereupon fever and pain immediately ceased The unnecessary wound in the mastoid healed in three weeks "[75] No one would use such a case as an argument against complete removal of all disease in the temporal bone, and no one, I trust, would select the operation I have just described on the sinus and vein for the relief of a local process in the temporal bone In dealing with a case our measures must correspond to the actual condition from which the patient is suffering

2 It has already been shown that the surgical treatment should be the same whether the disease has had its origin in an acute or in a chronic inflammation and that the dealing with the inflamed sinus and the inflamed vein in a manner comparable to the proper surgical treatment of acute inflammation in other parts of the body by free incision or ablation is not only not dangerous but highly beneficial and curative

3 In all great operations, in which

> All the shrouds wherewith my life should sail
> Are turnèd to one thread, one little hair "[76]

speed is an essential factor in success and grants to the eager surgeon

> ' Commandment on the pulse of life "[77]

In such an operation as I have described rapidity of skilled execution is as urgently needed as in general septic peritonitis from perforation or as in hæmorrhage from rupture of the spleen or the rupture of a tubal pregnancy As germane to the subject of despatch in operating I may quote from a writer who in criticising an operation which had been needlessly prolonged says "Such slowness is no result of justifiable caution but shows want of dexterity and imperfect knowledge of the operation region and the want of self confidence arising therefrom "[78] During an operation

> "Fearful commenting
> Is leaden servitor to dull delay "[79]

> "Away then! work with boldness and with speed,
> On greatest actions greatest dangers feed "[80]

To sum up may I again emphasise the fact that I am profoundly convinced of the value of arresting the current of venous blood which flows from the infected area I strongly urge its curative value, its imitation of the processes of nature, its harmlessness as an operative procedure, and its foundation on a true appreciation and knowledge of pathology It does not appear to me to be a moot question of surgical detail but is in accord with fundamental surgical practice The risk of leaving the vein unoccluded must not be run

On the walls of a famous clinic is emblazoned the legend—

> Ohne Glück und Gunst ist Weisheit und Kunst umsunst "[81]

There appears to be a hidden meaning in these words beyond that conveyed by the ordinary English translation—"Without luck and favour [grace or protection] knowledge and art are in vain"—perhaps somewhat akin to the thought expressed by the Psalmist

> "Except the Lord build the house: their labour is but lost that build it
> Except the Lord keep the city the watchman waketh but in vain "[82]

From the surface meaning of the words, as applied to surgical practice, I entirely dissent If under modern conditions a new wound heals by first intention the surgeon has but done his duty and luck and chance do not come in, but if the wound suppurates the surgeon has no justification in assigning the disaster to chance or luck. The circumstances of the operation must be carefully investigated so that the cause of the failure to obtain primary union may be discovered and that measures may be taken to avert the calamity of suppuration from future wounds

Körner[83] says "Experience disproves the dictum of Schwartze that for successful operation on brain abscess less depends upon method than upon luck, quite apart from the fact that there is absolutely no operation concerning which more depends upon luck than upon method."

In dealing with the lethal process of lateral sinus pyæmia and septicæmia luck and chance are poor substitutes for knowledge, skill, and determination.

> " In the reproof of chance lies the true proof of men "[84]

To you assembled here I would say—

> Out out, thou strumpet Fortune! all you gods
> In general synod take away her power '[85]

> ' First follow Nature, and your judgment frame
> By her just standard, which is still the same
> Unerring NATURE still divinely bright
>
> At once the source and end, and test of Art."[86]

"Between vague wavering capability and fixed indubitable performance," says Carlyle,[87] "what a difference." The conduct of the operation, no light matter even in the more simple of the cases under consideration, in the graver instances demands a sustained mental, and indeed physical, effort, the severity of which can only be appreciated by personal experience Too often when a patient is first seen

> A huge infectious troop
> Of pale distemperatures and foes of life [88]

have already wrought such havoc that

> ' Life is set at a pin s fee ' [89]

A NOTE ON ALBINISM, WITH ESPECIAL REFERENCE TO ITS RACIAL CHARACTERISTICS AMONG MELANESIANS AND POLYNESIANS.

BY C. G. SELIGMANN, M.B., M.R.C.P. LOND.,
SUPERINTENDENT OF THE CLINICAL LABORATORY, ST. THOMAS'S HOSPITAL.

WHILE in Torres Straits and New Guinea in 1898 as a member of the Cambridge Anthropological Expedition the opportunity arose of studying a number of albinotic subjects who uniformly differed in certain characteristics from European albinos. Reference to the most authoritative records of observers in the Pacific Islands showed that these characters had been noted wherever albinism had been recorded among a Melanesian or a Polynesian population, so that it seems reasonable to suggest that the type of albinism occurring among the races alluded to is as much a racial characteristic as height, skin colour, or cephalic index. That it is less variable in different stocks of the above races than the qualities mentioned will appear when considering in greater detail its geographical distribution. It may be noted that leucoderma of an exceedingly definite type is very common throughout the whole of British New Guinea, including the Western tribe of Torres Straits who, although belonging politically to Queensland, are most certainly Papuans.

Albinism as seen among Papuans is always of the type referred to, for the choroid is never pink and the hair is more or less tow-coloured, the skin varies from a pink white colour to that of *café au lait*, while the eye is generally greenish, hazel, or brown. The hair is no finer or silkier than in the normal Papuan and being frizzly keeps strictly to the racial type except as regards colour. With a light greenish eye there is usually associated a pinkish white skin certainly pinker where unexposed than that of the normal North European. The obvious expedient of calling this condition "incomplete albinism" or "partial albinism" has been avoided since the latter term has already been applied by Ziemssen, Crocker, and others to those cases in which there is congenitally a complete absence of pigment over more or less limited areas of the body and which can only be distinguished from the far commoner leucoderma by their congenital history. Finsch,[1] who saw at Kerapunu and Bulaa (Hula) examples of the condition under discussion, at first called these individuals "*weisse Papuas*" but subsequently dropped this term and wrote of them as albinos.[2] These subjects show great intolerance of sunlight and certain albinos of this type suffered far more from photophobia than did a North European with apparently similar pigmented eyes under identical conditions. They may be noticeably duller mentally[3] and less active in their movements than their normal fellow-countrymen; they seem to possess more subcutaneous fat and their skin may feel thick and harsh.

Turning now to the geographical distribution of the condition, and ignoring for the moment my own observations, Finsch[4] met with such albinos near East Cape at the extreme south-eastern extremity of the Possession and also in German New Guinea.[5] As already mentioned he saw similar cases at Bulaa and Kerepunu in the Rigo district. While at Hatan in Dutch New Guinea D'Albertis saw "a man ... accompanied by a son of about 25 and a daughter of about 20, both of whom were albinos; their hair whitey brown, their eyes blue, and their skin white like that of Europeans. He afterwards met ... a third daughter of the same man who was equally white."[6] Unluckily he makes no mention of the ancestors of this interesting family. At Fiji the members of the *Challenger* expedition saw "an albino boy who was perfectly white, his skin having a peculiar look, almost as if covered with a white powder in places. His eyes ... appeared as if the iris were of a pale grey colour. His parents said he could see perfectly."[7] In 1840 the United States Exploring Expedition at Vaturua in Fiji met with an individual whose "skin was dirty white and fairer than that of a European would be if exposed to the sun; he was marked with many brown spots about the size of a sixpence or less; his hair was of the same colour as that of the natives who use lime water for cleaning it; his eyebrows and eyelashes were of a flaxen colour ... the iris was blue with no tinge of red."[8] Subsequently the same expedition saw at Depeyster Island near the Ellice group two individuals the colour of whose skin was a "reddish white, the hair of a flaxen white with light blue eyes. ... They were covered in many places with large brown freckles";[9] the other members of the family were stated to be in no way remarkable. Finsch saw at Waikato in New Zealand a Maori woman with "light blonde" hair whom he at first sight took for a European. He does not state the colour of her eyes, but while he mentions that her sight was somewhat weak, the context does not suggest that her eyes were red.[10]

Nystagmus and jerky movements of the eyes were absent in all the cases of albinism I saw in New Guinea, nor does any previous writer mention their occurrence. This may perhaps be correlated with the superior visual acuity of Melanesian albinos as compared with that of those commonly seen in this country. The visual acuity of two albinos I examined at Bulaa was above normal, being $\frac{6}{4}$ and $\frac{6}{5}$ respectively. The former of these was the one-eyed man mentioned by Finsch. Mr. Nettleship, who has very kindly looked through his old notes, tells me that almost all his albino patients were amblyopic and had nystagmus, but that one albino—a man, aged 28 years—had a visual acuity of nearly $\frac{3}{6}$—i e., he could read, say, three out of 10 letters in the appropriate test-type at six metres This man's moustache was nearly white, his hair was very light, and his irides were blue grey His eyes, which were said to have been even lighter during childhood, yielded a red reflex by daylight and by focal illumination—that is, they were characteristically albino There was no photophobia or nystagmus, but these were elicited by ophthalmoscopic examination.

[3] This was especially noticeable in the boy Kilapelama and is not very uncommon in albinos of the Caucasian race. For the two following interesting family histories, which also bear on the heredity of the condition, I am indebted to Mr. E. Nettleship, whom I take this opportunity of thanking for placing at my disposal his notes on albinos lately attending his clinic at St. Thomas's Hospital. The first is that of a female, aged 10 years. Her parents, who are both described *as fair and* who are first cousins, have four children, the eldest of whom, a girl aged 12 years, has nystagmus and has suffered from fits. The next child, the patient, an albino, is dull and heavy but has not had fits. Her younger sister, aged eight years, is fair but not an albino; she cannot talk. There is also a brother aged *three months in whom no* peculiarities had been detected when the family came under observation. The second is that of a female, aged nine years. One of her maternal great-grandparents was an albino; *her mother is described* as almost an albino. The patient, who is semi-albinotic and suffers from hypermetropic astigmatism and nystagmus, is the eldest child. The next child, a boy, has been deaf and dumb *from birth*; two younger children show nothing unusual.

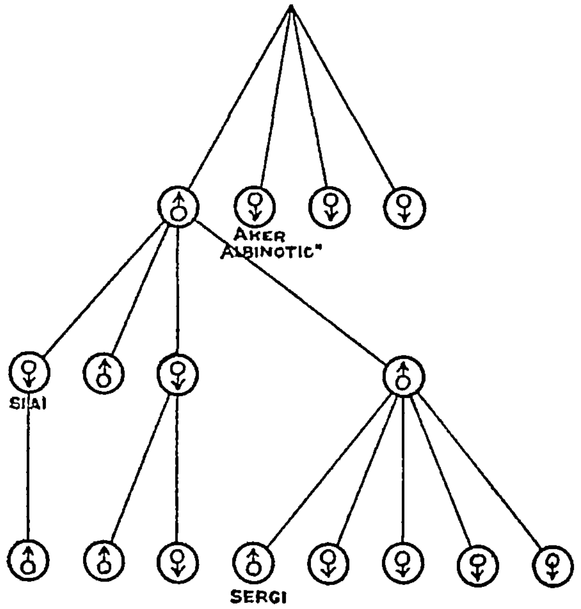
[10] Zeitschrift für Ethnologie, loc. cit.

As in other races albinism among Melanesians occurs in special families and groups of families[11] Sometimes it is hereditary, as the following genealogical tree (Fig 1) obtained at Yam in Torres Straits indicates. This is, however, the only instance I have been able to find in which the most marked type of albinism among Melanesians has been described as affecting more than one generation (Fig 1)

FIG 1.

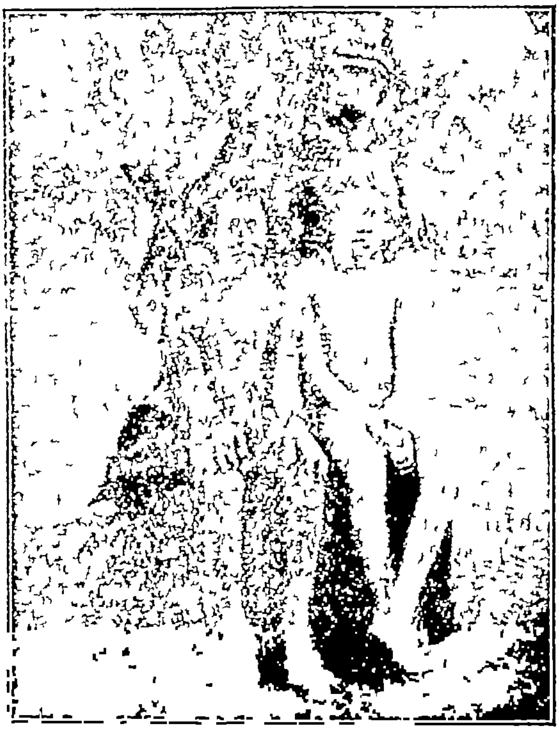


Pedigree chart showing albinos In this chart the individuals represented in each generation are probably not given in their correct order of birth.

The above scheme may almost certainly be taken as correct, for although Sergi's putative father does not belong to this albino family there is little doubt that Sergi does Siai and Sergi were seen, Aker—who is dead—was described as having been very light-skinned, though not a typical albino, and as having been affected with marked leucoderma beginning about puberty

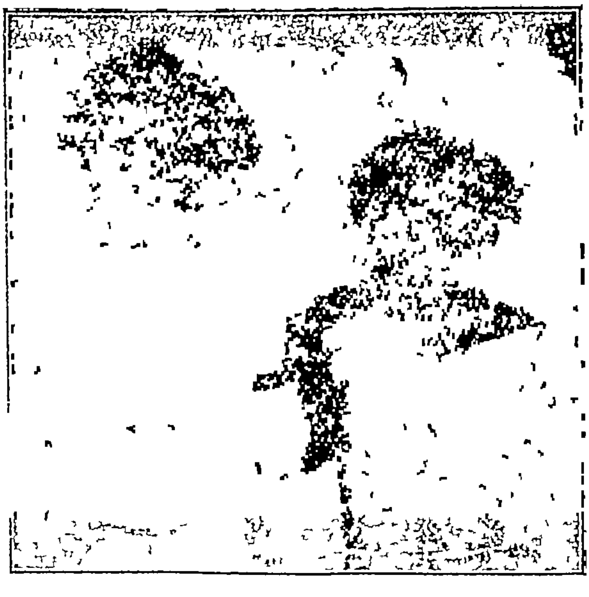
Siai, who was judged to be about 25 years of age, had tow-coloured hair and eyebrows her eyelashes were a trifle darker, while her axillary hair—in the normal native of a deep brown black—was light tow coloured. The colour of her skin[12] generally was about midway between No 5 and No 6 in the chart given in "Notes and Queries on Anthropology," that of her face was rather yellower, probably from the effects of exposure to the sun, and, perhaps owing to the same cause, felt somewhat coarse and harsh to the touch. The palmar surface of her hands and, to a less degree, the plantar surface of her feet, were remarkably pink, more so than is usually the case in white women.

FIG 2



Kilapelama and normal Bulaa boy (from a photograph by the late Mr A. Wilkin)

FIG 3



Kilapelama and normal Bulaa boy (from a photograph by the late Mr A Wilkin)

When seen she was suckling, her nipples were pinkish, their areolæ being rather darker, but both lighter than in many Anglo-Saxon brunettes Her irides were of a very light brown and photophobia did not seem to trouble her Her nephew, Sergi, aged about seven years, had hair, eyebrows, and eyelashes of the same colour as his aunt's The eyelashes were somewhat unusually long and curved upwards towards their free end. His body and forehead were covered with short very fine white hair The skin of his face was rather lighter than that of No 5 in the chart above referred to the skin on his body was darker and less yellow than that of his face. His irides were light brown He, too did not seem to suffer from photophobia.

---

[11] Crocker (Diseases of the Skin, 1893) says Heredity is the only known cause of the complete form and this in the shape of family prevalence as where there are several children in a family more than one are almost sure to be albino and Lesser knew of a family where six out of seven were albinos" Dr E Stainer who has collected from literature the history of 61 European albinos tells me that these cases 37 of whom were male and 24 female occurred in 19 families In nine families brothers and sisters only of the observed albino were albinos, in five families other relatives were albinos while in the remaining five families isolated cases appeared without any family history In New Guinea, of 14 albinos seen by Finsch, D Albertis and myself 10 were male and four female. They occurred in nine families; in two of these brothers and sisters were affected and in five individuals only while in the remaining two the condition absent in brothers and sisters appeared in the next generation.

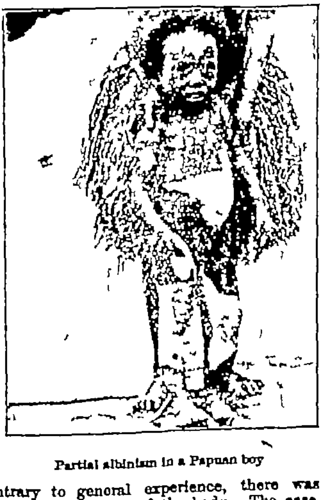
[12] The Yam women being Christians wear a loose dressing-gown like garment which incidentally protects the body from sunburn

An albino boy, named Kilapelama, aged about 10 years, seen at Bulaa on the south-east coast of British New Guinea, had, with a light, greenish brown iris, an especially pink white skin covered with short, fine, almost downy white hairs. Scattered over the whole of the body there were a number of irregularly circular patches of dark pigment, varying in size from that of a split pea to that of a sixpenny bit (Figs 2 and 3) The periphery of a certain number of these showed irregular dendritic processes of pigment On drawing the finger over the skin no difference in texture could be perceived between the general surface and the pigmented patches, the latter, which were, if anything rather darker and more bronzed than the skin of a normal Bulaa man, seem to be of the same character as those seen in the Vaturua case described by the American Expedition. Mr Norman H. Hardy has given me a photograph he obtained in Sydney of the head and upper half of the body of a man of Aoba in the New Hebrides in whom the black spots are so numerous as to produce a speckled appearance, the colour of the hair is not recorded, but judging from the photograph it was not of the usual black colour Other instances of the same condition have been described by Finsch. They were observed at Bulaa and in his paper already alluded to full details of Bulaa and Kerepunu albinos will be found.

There exists also a somewhat less-marked type of albinism in which greenish eyes and tow-coloured hair accompany skin of a pale *café-au lait* colour Two examples of this condition were seen at Jokea in the persons of a boy about 18 years of age and his paternal uncle. They were both lean muscular active, and energetic and the boy was of rather unusual intelligence. Neither suffered from photophobia to any marked degree nor was their skin harsh or thickened to the touch. This form would seem to denote a transition to those individuals not uncommon among the Papuans of Torres Straits in whom the skin is a shade or two lighter than is normally the case their eyes being brownish and distinctly lighter than the normal dark colour Their hair too is less dark and in the men this may be specially obvious in regard to their moustaches The condition tends to be hereditary all the children born to a Mabuiag couple, both members of which were of this type, were specially light-coloured.

Partial albinism is rare. Only one case was seen and in this contrary to general experience, there was marked symmetry on the two sides of the body The case was that of a Sinaugolo boy aged about four years (Fig 4) on whose trunk there was a large white patch, there was another somewhat diamond shape flare on his forehead reaching on to the hairy scalp, where the hairs were white. There were almost symmetrical patches just above the elbows on the back of the arm, while on both legs there were white areas extending from just above the ankles to the mid thigh. Dotted about these there were a few small roughly circular areas of normally black skin. There was no family history of albinism of any grade or of any unusual skin condition. My thanks are due to Mr A. C English, Government Agent of the Rigo district, who kindly photographed this case for me. The heaped up ulcer on the abdomen is the remains of a yaw tubercle.

FIG 4



Partial albinism in a Papuan boy

Leucoderma, which as already stated, is remarkably common and is generally distributed throughout New Guinea and Torres Straits as in other localities, tends to be symmetrical and is a disease of middle and advanced life. The borders of the white patches are always sharp and the bleaching is not as a rule preceded by an increased deposit of pigment. In one case only—that of an old woman one of the very few natives still left on the island of Nagir in Torres Straits—was the skin at the edges of and between the pale patches on the hand and forearm distinctly darker than over the rest of the body In all cases which were seen the disease was limited to the limbs, beginning always at the distal extremities and spreading slowly upwards, seldom reaching higher than the middle of the tibia in the lower limb or than the middle of the upper arm in the upper limb. The disease attacked the dorsum of the foot and the flexor surface of the wrist or hand far more commonly than the plantar and extensor surfaces respectively and very commonly began accurately opposite the flexure of the wrist, thence spreading up and down the limb In no case could any alteration of sensation or any trophic change be detected in the affected areas, nor was there any evidence of the change being due to vegetable parasites.

St. Thomas's Hospital, S.E.

PERSISTENT HEREDITARY ŒDEMA OF THE LOWER LIMBS

BY H. D ROLLESTON M.D CANTAB. F R.C.P LOND.,

PHYSICIAN TO ST GEORGE'S HOSPITAL SENIOR PHYSICIAN TO
OUT PATIENTS VICTORIA HOSPITAL FOR CHILDREN;
EXAMINER IN MEDICINE IN THE UNI
VERSITY OF DURHAM

I HAVE recently had under my care in St. George's Hospital a brother and a sister (patients of Dr H. Hollis of Wellingborough) who were both the subjects of a peculiar form of œdema of the legs. The œdema was permanent as long as they led an ordinary life and got more marked after exercise or a warm bath, but disappeared after rest in bed for some days. It was only troublesome from the weight and size of the swollen legs and did not give rise to pain or to any other bad results The mother aged 45 years, who had suffered for 35 years from the same condition, had long ceased to think of her own legs and was only concerned for her children. There were five other children, both older and younger but they were not subject to swollen legs or to chilblains. None of the mother's brothers or sisters survived infancy and this condition, which had apparently been transmitted from the mother to her two children could not be traced any further There was no history or trace of syphilitic infection in any of the patients. Some years ago a fatty tumour had been removed from one thigh of the mother by Mr A. A Bowlby There was no evidence of hæmophilia. The œdema was limited to the lower extremities and chiefly to the legs and feet. It varied, as already pointed out, gradually increasing when the patients were up and slowly receding when they remained for some days in bed, but there was no sudden appearance of the swelling as in [illegible] neurotic œdema. When the limbs were kept warm the [illegible] was natural in colour but the circulation was very [illegible] pressure on the skin leaving an anæmic area for [illegible] longer time than in normal persons. The œdema [illegible] pitted fairly readily and was distinctly cold [illegible] In appearance the skin was quite free from [illegible] change there was no thickening such [illegible] elephantiasis. The absence of any [illegible] mother in whom œdema had existed [illegible] remarkable. There was no tenderness [illegible] swollen parts There was no pain [illegible] or any part of the body except [illegible]

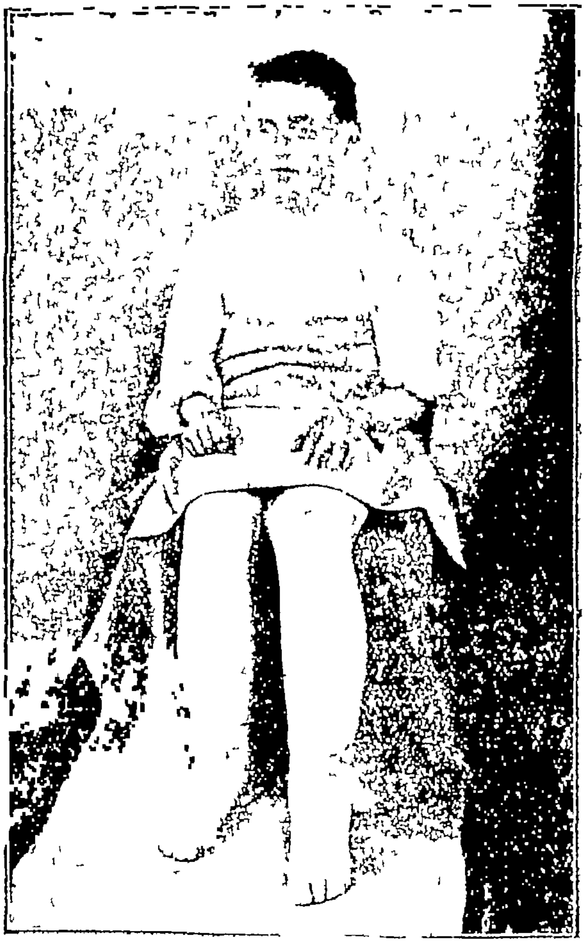
No recognised cause for œdema was forthcoming in any of the three patients Examination of the heart showed nothing abnormal and there was no anæmia, in fact, in both the brother and sister the number of red blood corpuscles was 5,800,000 per cubic millimetre. The urine was healthy, there had been no hæmoglobinuria and no signs of pressure on the inferior vena cava, or of lymphatic obstruction, venous thrombosis, or peripheral neuritis could be found They had not been out of England and had never had erysipelas, and they were not subject to urticaria or to any gastro-intestinal disturbance such as is common in angio neurotic œdema. There was, however, evidence of what was popularly called "a feeble circulation" At birth they were both "blue children," and were very subject to chilblains, both the feet and hands readily getting livid by cold When the skin was in this condition it resembled the stage of local asphyxia in Raynaud's disease The phenomena of local syncope, gangrene of the extremities, or hæmoglobinuria, had not, so far as history and observation went, occurred in these two patients The lividity and blueness of the hands were exaggerated, as in erythromelalgia, when they were allowed to hang down, and diminished when they were elevated But there was no pain or tenderness associated with the lividity, thus differing from erythromelalgia. Pressure on the congested skin left an anæmic area for a considerable time The patients were healthy looking, intelligent, thin, and perhaps a little small for their ages A few further details may be recorded about their condition

The girl was aged 16 years Swelling of the legs began three years ago and had been constant except when confined to bed for a few days When the legs had been bandaged the œdema had mounted to the thighs On July 8th the following measurements were taken the left calf, maximum measurement, 13½ inches circumference, the right calf, maximum measurement, 16½ inches circumference. A fortnight later, after being in bed most of the time, the right calf measured 12 inches and the left 11½ inches in its maximum circumference The urine was healthy The blood showed 5,830,000 red and 16 000 white corpuscles per cubic millimetre, a differential count showed a slight diminution of the polymorphonuclears and a corresponding increase in the lymphocytes Blood pressure at the wrist taken with Barnard's sphygmometer was 125 millimetres of mercury, or just about the normal

The boy was aged 13 years. His legs began to swell three years ago The œdema occupied both legs and ascended about half way up the left thigh. On admission, on May 28th, the following measurements were taken left calf, maximum, 12¾ inches circumference, right calf, maximum, 13 inches circumference On June 13th, after rest in bed with the end of the bed raised by blocks and treatment with ergot and digitalis in small doses, and galvanism, as practised by Sir T Barlow[1] in Raynaud's disease, the maximum circumference of the right calf was 11 inches and that of the left was 11¾ inches. The skin of the legs showed no structural change and no resemblance to elephantiasis. The creasing of the skin above the ankles shown in the photograph, kindly taken by Mr J W Mercer, was due to the pressure exerted by boots The knee jerks and sensation were normal. On exposure to cold the extremities became cyanotic, this was exaggerated when the hands were allowed to hang down The specific gravity of the blood was 1056 and the blood pressure, taken when the hands were warm by Mr Golla by Barnard's sphygmometer, was 95 millimetres of mercury, or below the normal The red blood corpuscles were 5 800,000 and the white 16 000 per cubic millimetre, with a diminution in the polymorphonuclear and an increase in the mononuclear forms. The urine was natural. On July 22nd he unfortunately developed scarlet fever and was transferred to a fever hospital.

Treatment consisted in rest in bed with elevation of the bed, and though drugs and the application of the constant current to the œdematous legs on the lines indicated by Sir T Barlow in Raynaud's disease were employed, position appeared to be the only thing which really had any definite effect on the œdema. Small doses of digitalis and ergot were given with the intention of improving the vascular tone.

Remarks—The occurrence of hereditary angioneurotic œdema is well known. Osler[2] has given a description of a family in which that disease was present in five generations, and quite recently Wardrop Griffith[3] has recorded a case of hereditary angioneurotic œdema which suddenly proved fatal from acute laryngeal œdema. The cases under my care differed entirely from angioneurotic œdema and superficially present more resemblance to the œdema of cardiac disease or of chlorosis. But there is no evidence that the œdema can be referred to either of these causes. The cases appear to resemble the remarkable family described by Milroy[4] of Omaha in which out of 97 individuals in six generations 22 persons (12 males, seven females, and three unknown) had solid œdema of one or both legs without any special inconvenience or progressive increase in the disease. The condition was congenital except in one case, in which it developed at the age of 12 years In one case only did the œdema disappear even temporarily. Crozier Griffith and Newcome,[5] in their paper on Types of Œdema in Infancy and Childhood, report a case which they regard as allied in some respects to Milroy's cases In a child, aged four years, œdema of the face and left leg developed at three months of age after measles Milroy, after very tentatively suggesting that the condition might depend on a congenital absence of valves in the veins, came to the conclusion that it was more closely allied to angioneurotic œdema than to any other known disease. My cases, however, differ from Milroy's in developing at or after 10 years of age They are therefore hereditary but not congenital in addition, as were all but one of Milroy's.



Shows persistent hereditary œdema of the feet, legs, and left thigh and cyanotic condition of the hands The creasing of the skin above the ankles was temporary and was due to the pressure of boots The patient had been up for some hours before the photograph was taken in order to increase the amount of œdema.

The disease in some respects resembles both Raynaud s disease and erythromelalgia but differs from them as has already been pointed out, in many essential particulars

The pathogeny of this curious condition offers a wide and tempting field for speculation It might be suggested that the persistent tendency to œdema from gravitation depends on some inherent defect or peculiarity of the small blood vessels which allows excessive transudation to occur on very slight provocation. Isolated examples of œdema for which no satisfactory cause can be found come under observation from time to time. I had a case of this apparently idiopathic œdema in a healthy young woman, aged 24 years under my care in St. George s Hospital last year and I have heard of a few other cases in women. Œdema of obscure origin is less rare in the newly born and in very young children and may be due to a number of different causes, but some of the cases where no satisfactory cause is forthcoming may be sporadic examples of the condition described by Milroy

The object of this paper has been to attract attention to a definite group of cases characterised by persistent œdema of the lower extremities which is hereditary and may be congenital but does not depend on any of the factors ordinarily recognised as responsible for œdema.

Upper Brook street W

MUCIN AND MALIGNANCY FACTS AND THEORIES

BY WILLIAM STUART LOW F R.C.S. ENG

ASSISTANT REGISTRAR TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

No substance in the animal economy has been more despised and neglected of medical men than mucin, but it may yet be destined to become the head of the corner Mucus has ever been the butt and *bête noir* of the physician whose every effort has always been strenuously put forth to brush, to wash and to dissolve it away as an evil thing serving only to harbour organisms and to retard and to jeopardise recovery from pathological conditions. How far wrong this depreciatory estimate of the value of mucin is an attentive study of its nature functions, and probable ulterior destiny will amply bear out. Mucin is the substance that gives the sliminess to mucus. It is very largely present in the system and is found under two conditions—first, almost universally distributed as the cementing material between cells—tissue mucin. This separates connective tissue cells and endothelial and epithelial cells even where most closely approximated. Normally there is always a layer however thin of muciginous material which separates the constituent cells in every tissue and membrane throughout the body and secondly mucin is found on all mucous membranes in mucous glands and in many epithelial and all special goblet cells, conspicuously so in the surface cells of the stomach wall where every cell is mucus secreting

There are probably several mucins in the body They are of a colloid nature, viscous, soluble in alkalies, but precipitable from such solutions by acetic acid. On boiling with dilute mineral acids they yield a substance which reduces Fehling s solution, and by appropriate processes mucin is broken up into a carbohydrate called animal gum and a nucleo proteid. Mucin has been specially investigated in the jelly like connective tissue of the vitreous humour the Whartonian jelly and in tendons While the part that mucin plays is doubtless largely mechanical in lubricating and protecting mucous surfaces, its peculiar chemical constitution and behaviour lend support to the belief that it has some further function. Physiologists mostly agree that mucin is not broken up in the digestive process but that it passes by the bowel unchanged. The very large amount secreted however and the comparatively small amount excreted would indicate that much is destroyed or absorbed in the small intestine, and the great additional supply in the large bowel supports this supposition and further nucleo proteid with its valuable percentage of phosphorus, being a result of mucin disintegration, the likelihood is that this is not thrown away but is absorbed from the intestine for ulterior use in the economy Where mucin is found fulfilling chiefly a lubricating function as in the gall bladder and bile ducts, in the pancreatic duct, and the lower bowel, it has a distinctly alkaline reaction and is mixed with the contents passing over the mucous surface On surfaces bathed by acid fluids, on the other hand the mucin is diminished in alkalinity and in this manner it is maintained on the surface proper for protective purposes this is well seen in the case of the urinary passages where much mucus is present and necessary Such is a wise provision for should the urine become alkaline the mucus present in it becomes then a serious factor in treatment. In the stomach again the acid gastric juice maintains the mucus on the surface the protective function being paramount. On the mucous membrane of the nose and other air passages the mucus plays a most invaluable part. It maintains moisture and conserves warmth, thus facilitating sensation both common and special. It also keeps the membrane fit both to catch foreign bodies (dust, bacteria, &c.) as the air filters through and serves to secure such until the leucocytes can annihilate or remove them.

One of the most important actions of mucin and one which has hitherto been altogether overlooked is as a bactericide This germicidal power was proved in researches I had carried out two years ago in the Laboratory of Clinical Pathology Queen Anne street, W by Dr G L Eastes. It was shown that mucin has a retarding influence on bacterial growth that sterilised solutions containing mucin remained sterile for a long time on exposure to the air and that bacteria ceased to grow in culture media when mixed with mucin. This is very interesting and instructive and proves that nature has in the secretion poured out on mucous membranes provided a ready means of suppressing bacterial growth. In the *British Medical Journal* of March 8th last there is an account (quoted from the *Lyon Médical*) of a research by Professor Fernand Arloing in which this work is repeated. From this he concludes that the mucus of red snails has a bactericidal action on the bacillus of Löffler and other bacteria and nasal mucus was found to be a bactericide for staphylococcus and pneumococcus, but not for coli bacteria or for Eberth s microbes. It must be evident, therefore, that mucin fulfils a potent part in the defence of the body against bacterial attack.

The essential lesion of carcinoma is the penetration of cells into the surrounding tissues, but whether this new departure on the part of the cells is a result of a cellular change or of some alteration in the intercellular resisting substance is not yet clear The probability is that there is a certain degree of both. In old age the intercellular material undergoes a wasting change and as a result of this its resistive power against the ingrowth of epithelial cells is lessened and thus the onset of carcinoma is favoured—particularly as the overlying epithelium remains much longer active and thus there is an influence inducing the cells to penetrate inwards among the tissues. The centrosome in cells on epithelial mucous surfaces occupies that part of the cell nearest the surface and therefore the part most exposed to injury and irritation. The centrosome is the dynamic centre and plays the leading part in the division of the nucleus and the proliferation of the cell and the regulation of movement.

A study of the distribution of mucous manufacturing structures reveals the striking fact that where mucus is least abundant their malignant disease is most located. This is the case where skin and mucous membranes meet at the edges of orifices as at the lips prepuce and anus, in the pharynx below the middle, as there are many fewer mucous glands in this situation than in the upper part and on the tonsil, where there are but few mucous glands or cells even in the crypts Malignant disease is common in the upper third of the œsophagus where there are few mucous structures and very common in the middle third, where there are practically none it is least seen of any part in the lower third where mucous glands are numerous. The œsophagus is peculiar in being dependent almost entirely for its lubrication and protective coating on mucus passing down from above—from the nose and vault of the pharynx. I have observed a number of cases of malignant disease of the œsophagus and in these there has been much diminution of mucous secretion from above shown by the deficient action of the mucous membranes of the nose and pharynx and always too, chronic dyspepsia due to the same cause—too little mucous protective coating in the stomach. Malignant disease is most frequently situated in the stomach at the pyloric end, but although there is much mucous secretion here there are special reasons for this selection, it is the most dependent part and most subjected to injury by lumpy and improperly masticated food and constant irritation by the acid gastric juice and from the fact that these patients are usually the subjects of deficient mucous supply from above, chronic hypo myxia nasopharyngia et gastrica, which accounts for the diminished mucous protective coating in the stomach

Cancer is most seldom met with of any situation throughout the whole extent of mucous membranes in the *small* intestine and in the *lungs* As I have pointed out in previous writings,[1] there is more mucus poured into the small intestine than is to be found anywhere throughout the system , and the lungs have an abundant supply in the secretions of the lining membrane of the trachea and bronchi. The inspired air is specially cleansed during its passage through the middle of the nose, the pharynx, and larynx, so that if malignant disease is set up by irritants from without there is small chance of such gaining access in any force into the lungs The urinary tract, again, is wonderfully exempt from cancer and mucus is plentiful on the surface lining It is pathologically proverbial how malignant disease attacks and spreads in the mamma, but in this gland there is no mucus whatever, not even in the ducts No protection is here necessary from irritating secretions unless the milk were to become acid from the formation of lactic acid, and lubrication is not needed as fat is the dominant element in milk. In the salivary glands how rarely is cancer encountered, but mucin is largely present in them and an element of their secretion, notably so in the submaxillary and sub-lingual When malignant disease is met with in salivary glands the parotid with its very meagre amount of mucus is much the most frequently attacked The exemption of tendon and cartilage and the frequency with which bone is affected are also noteworthy The mucous glands of the uterus are mostly found in the upper two thirds of the organ which is the least frequently affected by cancer, but I look upon a uterus prepared for carcinoma as an atrophic one or becoming atrophic just as atrophic rhinitis commonly follows on hypertrophic The circumstance of frequent pregnancies is a strong predisposing cause This is the hypertrophic stage in the case of the uterus, and it is at the menopause when the atrophy sets in that malignant disease comes on, when there is a hypo myxiatous condition set up

During the last few months I have carefully observed 15 cases of malignant disease (see below) and have been struck by the fact that all have shown evidence of hypomyxia in varying degree I am indebted to a scholarly article by Dr Walker Overend in THE LANCET, where he was kind enough to mention my former paper on Mucin, for

TABLE OF 15 CASES OF MALIGNANT DISEASE

No	Sex and age	Occupation	Disease	Common salt	Tobacco	Syphilis	Hypomyxia
1	M , 66	A ' backer of horses" much indoors and in close rooms	Malignant of the rectum	Taken an excessive amount over 40 years	Smoked cigars cigarettes and a pipe to excess	Yes	Has suffered from well marked hypomyxia naso-pharygea, gastrica et colica for 30 years
2	M 30	Labourer with the National Telephone Company much in dust at underground work	Sarcoma of the tonsil	Taken an excessive amount all his life, a great meat and bacon eater	An ounce a day for years	"	Well marked hypomyxia naso-pharyngea et gastrica et colica and a rapid eater
3	F , 45	Housewife much indoors	Malignant of the liver	Always takes a good deal of salt	No	"	Hypomyxia naso-pharyngea moderately marked, but gastrica et colica quite evident
4	M 69	Worked for many years in a very dusty sugar warehouse	Sarcoma of the left side of the pharynx with a mass of glands in the neck	Has consumed a very large amount all his life	At least one ounce a day for 50 years, often two	Doubtful but was exposed to infection in his younger days	Hypomyxia naso-pharyngea very well marked and also gastrica et colica very evident
5	M , 51	Cabinet - maker in door work and often very dusty	Malignant of the pharynx and parotid region	Has always taken a very large amount	One ounce a day but often got through one pound a week	Yes	Hypomyxia naso-pharyngea et gastrica et colica very evident
6	F , 45	Housewife	Malignant of the omentum	Has always taken a good deal of salt and has had a ravenous appetite for shellfish	No	Doubtful	Hypomyxia naso-pharyngea slightly but gastrica et colica evident.
7	M , 65	Piano polisher indoor work and often very dusty	Malignant of the œsophagus.	Has always taken a large amount of salt.	Smokes over one pound a week.	Yes	Hypomyxia naso-pharyngea and gastrica et colica very well marked
8	M , 68.	Indoor messenger	Malignant of the œsophagus	Very large consumer of salt all his life	Smokes very large quantity	Doubtful	Hypomyxia naso-pharyngea well marked and gastrica et colica
9	M , 59	Carman on the Midland Railway often in foul dust	Epithelioma glosso-epiglottidean region	Very large amount all his life. Put it on salt bacon.	One ounce a day	Yes	Hypomyxia naso-pharyngea et gastrica et colica very well marked
10	M , 35	Newsagent (dusty indoor work)	Malignant lympho sarcoma of the cervical glands	Had always been fond of salt with his food	Half an ounce a day at least.	Doubtful.	Hypomyxia naso-pharyngea et gastrica well marked
11	M , 71	Hairdresser in the city underground and dusty	Epithelioma with enlargement of the glands in the neck.	Taken salt in large quantities for 50 years	Over an ounce a day, often more, for all his working life	Yes	Hypomyxia naso pharyngea et gastrica et colica very well marked
12	M., 65	Engineer in doors worked in iron dust.	Malignant of the œsophagus	Taken salt with all his food in large amount all his life	Over one ounce a day	,	Hypomyxia in nose and throat and stomach well marked
13	F , 41	Housewife always in doors"	Epithelioma of the tongue.	Very fond of salt and had taken it in large amount	No	No	Hypomyxia in nose throat stomach, and bowels evident
14	M , 28	Broker s clerk underground dusty office	Sarcoma of the tonsil	Always taken salt in large amount	Smoked nearly one ounce a day	Yes	Hypomyxia naso-pharyngea et gastrica.
15	M., 43	Dustman (very dusty work)	Carcinoma of the pylorus	Taken an excessive amount of salt always.	Smoked one ounce a day for years	"	Hypomyxia well marked in all the usual situations

---

[1] Mucin in Desiccation Irritation and Ulceration of Mucous Membranes THE LANCET, Oct. 12th 1891

the nomenclature which here I have adopted. The term ortho-myxia is used to express a perfectly sound and healthy state of the mucous membranes and their secretions. Quantitative change may be termed 'meta myxia, where the change is in excess the term 'hyper myxia is used The converse condition would be hypo myxia, where there is a profound qualitative alteration then 'para myxia" would be most expressive. Dr Walker Overend uses the term myxasthenia comparable to anæmia and to neurasthenia, and I think quite rightly because when the local hypo myxiatous conditions have continued long enough the state of myxasthenia is brought about. In hypo-myxia naso-pharyngia there is a history of the patient seldom or never using a handkerchief never having occasion to blow anything from the nose and there has in all seasons been a marked freedom from colds in the head. I have had cases where there has been irritation felt in the nose and frequent blowing induced and still with hypo-myxia present, but these have been instances of spur or deflection of the septum or other such condition I have usually *tested the hypo-myxiatous patient* by requesting a trial blow of the nose into a clean cloth nothing being expelled or at most a little watery fluid but never the healthy mucus that can usually be readily extruded by the ortho-myxiatous even when they happen to be octogenarians. An inspection of the interior of the nose in such hypo-myxiatous patients shows a general loss of turgescence and vascularity of the mucous lining it may even be distinctly dry and crusts may be detected. The turbinals are small and sometimes shrivelled, especially the inferior one, and this is most noticeable on both turbinals posteriorly where most of the mucous secretion takes place. The cavity of the nose is more or less roomy The fauces and pharynx display similar symptoms of lessened mucous discharge. Occasionally the posterior wall of the pharynx shows the para myxiatous change in the form of streaks and tracks of altered mucus This state of the naso-pharynx is often accompanied by a similar condition of the gullet and stomach—hypo-myxia gastrica, with its attendant symptoms of dyspepsia and flatulency and sometimes constipation, the constipation being due to a like alteration in the large bowel —hypo-myxia colica—but this varies greatly in degree.

Now every one of the cases of malignant disease that I refer to and made note of were hypo-myxiatous to a varying extent, and as most of these were instances of the mucous membrane of the alimentary or upper respiratory tract being affected, I am inclined to believe that there is a connexion between the two states, and that the hypo-myxiatous is a forerunner of the cancerous, especially in view of the fact that three-fourths of all cancer in man occurs in the alimentary canal.

Two features more I made out common to nearly all of the 15 cases of cancer—the first, that they were nearly all much addicted to tobacco-smoking consuming from one to two ounces a day and secondly were large salt-eaters. Two of them were so addicted to salt-eating that they even had it sprinkled on salt bacon. Both of these habits tend directly to bring about the hypo myxiatous state. The hot tobacco smoke for a time stimulates the mucous glands, but soon causes desiccation and atrophy and excess of common salt is pernicious, because it precipitates and coagulates the mucin and causes an impairment of secretion. The essential factor in cancer being intrinsic—a weakening of the inter-cellular resistance, so that the cells when proliferating can also penetrate into the inter cellular spaces and substance—it may be that a myxastheniatous condition of the tissues favours, if it does not cause, this loss of resistance. Normally as before remarked, there is always, even when reduced to a minimum a layer of mucinous material between cells everywhere in the body and it is possible that this is maintained in its natural tonic resisting state by an internal circulation of mucinous matter from the intestine to the tissues. If this be so a prolonged diminution of mucin in the alimentary tract would account for a deteriorative change upsetting the equilibrium between the cells and the inter-cellular tissues. With tissues thus prepared the effect of an *injury* or *chronic* irritation might be to determine such a morbid process as carcinoma or sarcoma, whereas in the healthy (ortho-myxiatous) these would induce no such changes however long continued, but might cause only a harmless inflammatory action. This theory might also be made use of to explain why carcinoma is an affection of the decline of life hypo-myxia being a senile change.

I have lately been examining a number of very old people mostly old men I have found them all wonderfully ortho-myxiatous having healthy naso-pharyngeal mucous membranes, good digestion, and regular bowel action. I am inclined to believe therefore, that such is an insurance of healthy old age. I certainly have not yet seen one healthy old man who was not ortho-myxiatous, so that one is warranted in reckoning this as a condition favouring longevity I recently examined a man aged 96 years, who was sent from a workhouse to the Central Throat and Ear Hospital for slight deafness and tinnitus. He expressed himself as perfectly well in every way His mucous membranes were in good condition and all to be made out was in-drawing of the tympanum of both ears. I had no doubt that this was due to a senile change in the middle ear from desiccation of the mucous membrane, thus also accounting for the tinnitus. This was shown to be the case by the success of the treatment—viz. injection of warm mucin solution up the Eustachian tubes with markedly successful result, as his hearing improved at once and the tinnitus abated and after a few injections disappeared. This man was a non-smoker and took very little common salt. Hypo-myxia is hereditary The tendency to a varying extent of impairment of the mucous-forming function is occasionally very evident in early life and when so it is almost always hereditary either from one parent or both This is most noticeable at special hospitals as rhinitis and pharyngitis sicca and atrophica, as early as from five to seven years of age. I have notes of two cases of sarcoma in the bones of children who were both quite hypo-myxiatous, as were both their parents before them. The question arises, does this help to explain the strange and unaccountable occurrence of sarcoma in early life, and of congenital sarcoma, hitherto a baffling problem? In the following table of cases of cancer it will also be noted that in nearly every instance there was a history of syphilis It is very remarkable how the stress of secondary syphilis mostly falls upon the mucous membrane. It is notable how many hypo-myxiatous patients have had syphilis. May this throw any light on the obscure but admitted connexion between syphilis and cancer? Cancer has been shown to be much more frequent among civilised than among savage peoples, among the denizens of town than in a rural population and in fact, to dog the footsteps of civilisation. This may be explained by the fact that much that is incident to town life is favourable to the development of hypo-myxia. Foul and often dusty air and bad ventilation especially in sleeping rooms are some of the most noxious influences. Although it has been found to be commoner in town dwellers, anyone with a hereditary hypo myxiatous tendency if in unfavourable surroundings will readily become hypo-myxiatous no matter how rurally remote he may reside. The Boers might be cited as a people well known to be very liable to cancer whose domestic sanitation is far from perfect but is most emphatically bad as regards the ventilation of their sleeping apartments. The immunity of the lower animals from cancerous processes is still unaccounted for Wild animals are very seldom affected and our domesticated animals but rarely It is proved that the domesticated animals most subject to cancer are not, as one might expect, the dirty feeding pig but those cleanly and affectionate friends and companions of man the dog and cat. They often share with man the same unhealthy surroundings and this doubtless to some extent explains their liability; another fact also helps to elucidate this obscure point, for the dog and cat possess much less provision for the formation of mucus than the horse, ox, sheep and pig Their turbinated nasal structures are excessively convoluted to enhance the sense of smell and so mucus secretion is a subordinate factor little or no mucin being ever formed in an olfactory region unless in very small amount. The fæces of the dog indicate but sparse mucous supply all along the alimentary canal. The horse ox, sheep, and pig have quite an extraordinary development of mucin forming organs

In the horse not only are both the anterior and posterior turbinated bones very well developed but each bone has a special fibro-cartilaginous *framework* extending to the external orifice of the nose. These turbinated bones are essentially so disposed as to furnish the mucous membrane of the nose with a vast surface and such flexible appendages are sometimes double. This free surface presents numerous glandular orifices and is constantly covered by an abundance of mucus that prevents desiccation. The upper one third only of this larger area is devoted to olfaction Racemose mucous glands are specially numerous on the area of the septum and the cartilaginous appendages (Chauveau) Besides this extensive secretory region solipeds have another special arrangement which also subserves mucus secretion, this consists of the so called guttural pouches, one on each side of the pharynx. They have each a length of four inches and a capacity of three-quarters of a pint Their mucous lining is thick and vascular and very thickly studded with racemose mucous glands Much mucus is secreted in these pouches and poured into the pharynx Few mucous glands are present in the horse's œsophagus, but it is well lubricated and protected by the copious supply from above, as all this mucus is swallowed, for the horse never has any discharge from the nose in health Jacobson's organ is five inches long in the horse and very thickly packed with mucous glands. The ox has also a vast development of the turbinated bones, especially of the posterior one, and besides there is an extra turbinal—the third turbinated bone of the ox. The sinuses of the head, particularly the frontal sinuses, which are very extensively developed, open freely into the meatus and afford an additional mucous secreting surface In the pig there is also a large mucous secreting area and the turbinated bones are very prolonged. The ox is constantly licking its muffle and thus swallowing the mucus escaping from the nose and removing the humid secretion with which it is always kept damp Chauveau in his comparative analyses of the domesticated animals gives the following table of the ratio of the area of the cranium to face 1 in 2 69 in the horse, 1 in 3 43 in the ox, 1 in 3 24 in the pig, 1 in 1 17 in the dog, and 1 in 0 68 in the cat Order cat, dog, horse, pig and ox. The face area may fairly be taken as a very good index of the mucus supply area. It will be noted that this area is much smaller in the cat and dog The horse s secreting area is very much supplemented by the secretion in the guttural pouches

TREATMENT

The first patient on whom mucin was used in malignant disease was a man (Case 5) who came to the Central Throat and Ear Hospital with a large mass of glands in the parotid and cervical regions and also a hard mass bulging into his pharynx. He was suffering great pain in the throat and up the neck to the head Mucin in the form of a gargle composed of soloid and tabloid mucin co, one of each dissolved in one ounce of hot water with a third of an ounce of lime water, gave him great relief and facilitated the swallowing of food Mucin feeding was ordered and he was told also to swallow the gargle. He thus consumed from 10 to 12 tabloids and the same number of soloids per day His appetite improved and his bowels—always very costive, only having an action about twice a week—soon became regular Although his case was a perfectly hopeless one from the first he certainly improved for a time and got great relief from this treatment. The mass in the neck broke down and a large ulcerated surface resulted This was dressed with a lotion similar to the gargle which kept the broken surface beautifully clean and sweet and greatly relieved the pain and diminished the discharges He lived three months and was able frequently to go out, but the growth spread to the lungs and he died from pneumonia The alleviation of the pain was certainly most marked, allowing the poor man to sleep, which he had been unable to do formerly

The second case was that of a man (Case 11) suffering from epithelioma of the pharyngeal wall in the lower part and having a mass of glands on the left side of the neck Mucin was ordered in a manner similar to that in the last case The pain was again greatly relieved and he was able to sleep well and had a good appetite and his swallowing was done easily The mass of glands diminished and at the end of one month s treatment there was a difference of two inches in the circumference of his neck Unfortunately he contracted a severe attack of influenza and died after three days' illness

A man (Case 2) had been under Dr P Abercrombie's treatment for one month at the Central Throat and Ear Hospital suffering from an induration of the right tonsil with a mass of glands in the neck. The case was going from bad to worse and Dr Abercrombie kindly allowed me to use the mucin treatment. The growth had extended on to the soft palate and had ulcerated, the jaw was fixed so that he could only separate the teeth a very little way, and the mouth and breath were very offensive He was also in great pain Mucin was used as a gargle and mouth wash and he was given mucin feeding The improvement was very marked indeed The pain ceased and the circumference of the neck diminished by three inches in one month (Feb 21st last) To hasten the process I injected one quarter of an ounce of a warm solution of mucin into the subcutaneous tissue of the back three times a week and occasionally into the mass of glands in the neck This treatment was continued for another month with good effect. The ulcerated throat cicatrised over and he could easily chew and swallow solids, so much did the jaw relax. He also gained seven pounds in weight. This favourable progress met with a check when the sites of two of the subcutaneous injections suppurated in succession. The reason for this I could not explain, as this condition had not occurred in the other cases, and every aseptic precaution was taken One singular thing was that, although the injections into the mass of glands were conducted in the same way and with the same fluid, yet never at any time had suppuration occurred There seemed to be a profound change in the tissues in the neighbourhood of the growth The growth continued now to increase both inside the throat and in the neck, although the mucin still gave him great ease from pain, not until May 30th last was it necessary to perform tracheotomy. Gastrostomy was done at the same time in St Thomas's Hospital, to which he was sent on May 28th The mucin treatment undoubtedly checked the growth for a time. This was proved to be sarcoma by microscopic examination The man is now home and still under mucin treatment.

Another case is that of a man (Case 4) who came to this hospital complaining of pains in the throat and up the side and back of the neck He has a mass in the right side of the pharynx, hard and elastic, bulging into the throat and there are glands on both sides of the neck. During the last three months he has been having mucin treatment with great relief to his pain and the enlargement has somewhat lessened His appetite has improved He is very hypo-myxiatous, but mucin spray and gargle have helped the pharyngeal discomfort, and his gastric symptoms are alleviated and his bowels are regular He is having mucin feeding but no hypodermic injections Dr Dundas Grant kindly allowed me to use mucin in this case

A man (Case 9) came to the Central Throat and Ear Hospital complaining of dysphagia, severe pain in the throat, and sleeplessness He was found to have an epitheliomatous ulcer in the glosso epiglottidean region, and there was a mass of glands on the left side of the neck The mucin treatment has given him great relief and enabled him to swallow much better and to sleep at night He is still under treatment.

Case 1 is one in which I have found mucin afford signal benefit One month ago I did an inguinal colotomy for malignant disease in the rectum on this patient As he is very hypo-myxiatous I had great trouble to maintain the bowels in regular action with soft stools, but mucin feeding to the extent of 12 tabloids a day—two before and two after each meal—has solved this difficulty most satisfactorily and also remedied the gastric irritation and flatulency This is a much better means of regulating the bowels in such cases than giving oily aperients, as it supplies the natural lubricant and never causes any griping pains or too much disturbance

These cases in which mucin was prescribed were all in an advanced stage before commencing its use, but yet there was improvement in each instance. In an early stage this improvement is likely to be better maintained, and in hypo-myxiatous patients who have been operated upon for cancer it might be tried to prevent the recurrence of the disease. Of course, tobacco and salt are peremptorily prohibited

THE CANCER PROBLEM

By W V SHAW, B A., B M, B CH OXON,
LECTURER IN PHYSIOLOGY AT ST JOHN S COLLEGE OXFORD LATE CASUALTY PHYSICIAN ST MARY S HOSPITAL.

TUMOURS and new growths have their origin in the proliferation of tissues the cell elements of which retain most of their morphological characteristics All newly formed cells arise from equivalent tissue elements This is the fundamental fact of cellular pathology Tumour formation is a progressive process continually diverging from the state of health It may be asked What is the most prominent characteristic of tumour cells as opposed to normal physiological tissue? It is that their vegetative functions dominate all other functions of the cell. Their reproductive activity overpasses that in any other direction

Malignant tumours—e g carcinomata—are characterised by a cell proliferation that, in its biological relations enters into opposition with the physiological tissues from which they are derived The more malignant the tumour in its clinical aspects the more does this proliferation and reproduction of the cancer cells become a prominent feature of the growth This is especially seen in the peripheral growth and penetration of surrounding tissues. Another important feature of these tumours is that they never reach maturity, they are never fully-developed tissues, structurally or otherwise. Degenerations are extremely common and testify to the unstable nature of the new growth.

What, then is the biological aspect of these conditions and what is the biological position of the cells? That the life-history of cancer cells is atypical cannot be doubted when the nuclear changes in these cells are studied. Abnormal mitotic figures are extremely common. Asym*metrical division of the nucleus is frequently observed.* In certain forms of sarcoma giant cells are a prominent feature. Hyperplasia of the nucleus and hyperchromatosis of certain mitotic figures are also characteristic of these new growths. These facts point to changes in the life-history of the cells. Again in carcinomata certain bodies have been observed in constant and close relation with the nucleus of the cancer cells. Some have considered these to be parasitic organisms causally connected with the changes referred to above. Others claim that these are degenerate portions of the nucleus or some endogenous structure formed from the nucleus. Assuming this latter explanation these bodies give a further indication of the abnormal protoplasmic activity of the cell

How then do the above nuclear changes influence the life-history of the cell? To the nucleus alone is assigned the perpetuation of the type and characteristics of the cell from generation to generation and when any alteration takes place in the nucleus there are corresponding changes in the cell. The nucleus plays an important and controlling part, not only in the process of cell-division, but in the functional activity of the cell.

Recent experiments have shown that the stimulation of the *ova of certain lowly-organised animals will* cause the multiplication of cells and the ultimate development of free swimming larvæ from such ova without previous fertilisation of the ova by spermatozoa. Adult organisms do not develop, but larvæ capable of independent existence can be produced This result has been obtained by acting upon the ova with strychnine and also by mechanical agitation of the ova. The multiplication of cells in these larvæ is comparable with the attempts at reproduction of tissue in partially *damaged* structures of which the giant cells in tubercle and the vascular connective tissue of healing wounds are examples. The growth of cancer cells is then to be looked upon as an effort of reproduction in damaged tissue, the incidence of the damage falling upon the nuclear structures This damage alters the nature of these structures so that the vegetative functions of the cell run riot, and the cells become parasitic towards the organism in which the growth is taking place. The nature of the changes in the cancer cells and their life-history thus becomes the important point from which the origin of the cancer process must be determined

What is the cause of this vegetative activity? Is it an initial damage to the cells in response to which there is an over active attempt at repair? The peculiar frequency of such disease in organs once active but now undergoing involution would suggest this explanation and also the frequent origin of malignant growths in damaged tissue further supports this view This is in accordance with Weigert's observations on the *over production* of damaged parts in the process of repair Hence in considering the etiology of malignant growths the causation of this vegetative activity must be investigated. It may be chemical as in the experiments with strychnine referred to above, or it may be biological, as in the theories that have been advanced as to the microbic origin of cancer The actual epithelial cells are the source of the infective process, as shown by the reproduction of the type of cell in secondary growths, and the penetration of the surrounding tissues by the epithelial cells.

This view of the importance of the cancer cells in a malignant growth is hardly in accord with the views of those who maintain that it is the degeneration of the surrounding tissues, particularly the connective tissue, that allows of the overgrowth of epithelial cells. But such a degeneration of the connective tissue has never been clearly demonstrated as a cause, and in the case of most cancers there is a considerable increase of the adjacent connective tissue. This hypothesis then draws attention to the nuclear changes in cancer cells and the consequent increase in the vegetative activity of these cells.

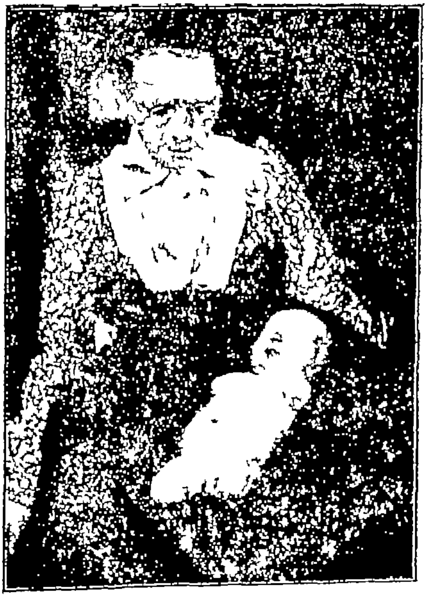
A CASE OF ECTROMELUS

BY JOHN MCGIBBON M.B. C.M. EDIN

THE accompanying illustration shows a female infant in whom both the upper and lower extremities are almost entirely absent. It is a reproduction of a photograph taken on July 7th, 1902, the infant having been born five days previously The stumps of the lower extremities end in fleshy nodules, but those of the upper extremities are rounded as after amputation. Bones can be felt in all the stumps. The child is the fourth in the family There is no history of shock or maternal impression and no trace of deformity in the other children of the *family or their relatives.* During the latter stages of pregnancy the mother suffered a good deal from pain in the abdomen. False labour came on and *persisted for* 48 hours before the os uteri relaxed, and because of this I was called to see the case by the midwife in charge. The child is healthy and vigorous The nose is quite red from birthmark.



A case of ectromelus.

The case is a rare one and seems to belong to Saint *Hilaire's class* Ectromélie ”

Liverpool.

DEATH FROM THE BURSTING OF A TONSILLAR ABSCESS

By ALEXANDER LYONS, L R.C P & S, EDIN

THE following may be of interest. A man, aged 28 years, was admitted by me into the *Torbay Hospital* at 9 30 A.M on August 13th suffering from a very large suppurative tonsillitis on the left side. He was given a warm bath and put to bed where he partook of a glass of milk. About half an hour afterwards the nurse in charge of the ward heard him coughing feebly and on going to ascertain the cause was surprised to find him cyanosed. She sent for me and I went immediately but the patient was dead when I arrived I do not think that more than five or six minutes could have elapsed between the time when the nurse heard him cough and my arrival at the patient's bed side.

At the post mortem examination I found that the abscess had burst and that a large amount of pus had got into the upper part of the larynx.

On looking up the literature on the subject I find only one case of a similar kind recorded—viz., by *Hilton Fagge.*

Torquay

A CASE OF FOREIGN BODY IN THE NASO PHARYNX.

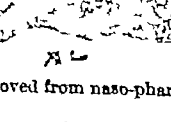
By RICHARD LAKE, F R.C S ENG,

SURGEON TO THE METROPOLITAN EAR NOSE AND THROAT HOSPITAL ETC

THE presence of foreign bodies in the naso pharynx appears to me, as far as I am able to ascertain, of sufficient rarity to justify the brief report of a case, although it is true that the symptoms did not amount to more than discomfort or inconvenience and that also in this instance the presence of the foreign body was not suspected

The patient, a married woman, aged 48 years, was sent to me in July, 1900, by Mr H. Beadnell Gill, who desired my opinion as to the question of involvement of any of the accessory nasal sinuses The history was peculiar For some years the patient had blown from the nose every morning either matter (probably muco-pus) or matter with hard offensive crusts At times these were, according to her description, covered with mildew The total duration of this trouble was about 14 years On examining the patient there was obviously rhinitis sicca et atrophica and the naso pharyngeal vault could be distinctly seen covered apparently with a crust of congealed mucus, blackish in colour The naso-pharynx was so irritable that it was impossible to get any view from behind

I did not see the patient again until March 3rd of this year, but when she came to see me, stating that she had a sensation of burning in the tongue, it was still impossible to get a look at the naso-pharynx. I then ordered the use of peroxide of hydrogen (10 volumes) to the vault of the naso-pharynx by means of a post-nasal syringe Three days later a large fragment of the wing of the seed vessel of the ash or sycamore was removed from the naso-pharynx by the patient. The accompanying figure represents the piece removed.



Foreign body removed from naso-pharynx (natural size)

It is impossible to say when this foreign body was introduced into the nose and it is also equally impossible more than to speculate as to whether the inflammatory condition of the naso pharynx was a result of its presence or whether the patient had suffered from some such condition before which had allowed of the foreign matter being more easily retained

It is hardly necessary to state that the patient's condition has been much improved now that it is possible for remedial agents to be directly applied to the vault of the pharynx.

SIDCUP COTTAGE HOSPITAL

A CASE OF SUPPURATIVE THROMBOSIS OF THE LATERAL SINUS, OPERATION, RECOVERY

(Under the care of Dr T M CALLENDER.)

THE treatment of the jugular vein in cases of middle ear disease is dealt with very fully in a paper by Mr C A. Ballance which appears in this number of THE LANCET, at p 795 Ligature of the jugular vein for sinus thrombosis appears to have been first suggested by Sir Victor Horsley [1]

The patient was a man, aged 38 years His previous health had been good His wife had recently died from phthisis He had three healthy children. He suffered from a "touch of the sun" six weeks before admission to hospital. On August 19th, 1901, he complained of a foul discharge from the right ear He also complained of general weakness but there was no pain in the head or tenderness over the mastoid The temperature on admission to hospital was 100 8° F, next morning it had fallen to 98 2° At noon of the following day he had a violent rigor and the temperature ran up to 105 8° and the pulse to 142. The patient became unconscious After consultation with Dr G W Davis and Mr H. A. Duffett of Sidcup Dr Callender decided at once to explore the mastoid and while getting ready to operate the patient was sponged with tepid water, with the result that the temperature was reduced to 102 2° and by the time he was on the operating-table he was conscious and consented to operation. A.C E. was administered. Dr Callender cut down on the mastoid, gouged away the bone, and found a quantity of foul pus in the cells, free communication was made between the wound and the auditory canal. The wound was douched and a gauze drain was put in The patient seemed better for 24 hours after operation, but on the following evening his temperature was 104° The discharge from the wound and ear was free and with cold sponging the temperature fell to normal. Next morning (two days after the operation on the mastoid) the patient had another very severe rigor and the temperature ran up to 104° He complained of stiffness of the neck, but there was no pain or tenderness over the internal jugular and no sickness. His breath was foul Dr Callender resolved to operate again and to explore the lateral sinus as it was evident that the entire source of the mischief had not been reached, the rigors and foul breath which were assumed as being due to pyæmic pulmonary complications (though no definite physical signs could be made out in the lungs at this time) making the diagnosis of suppurative thrombosis of the lateral sinus probable. A C E was again administered. Bone was gouged away over the lateral sinus A hypodermic needle was thrust into the sinus and a little sero pus was obtained, but no blood. The internal jugular vein was then cut down upon and ligatured, cutting between a double ligature. The sinus was opened freely, an opening was made in the upper end of the jugular into which was inserted the point of a No 8 gum elastic catheter, a ligature was put round the vein and catheter to prevent escape of the contents of the vein into the wound The lateral sinus was gently syringed from below upwards through a catheter with 1 in 4000 solution of perchloride of mercury A large quantity of very foul pus and clotted blood came from the lateral sinus The internal jugular vein was then ligatured above the opening made for the catheter, cut short, and the wound in the neck was closed. The lateral sinus was packed with iodoform gauze. The wound was dressed each day, douched out with 1 in 4000 perchloride, and packed with gauze The patient improved wonderfully after the second operation but several complications delayed convalescence. He developed a large pyæmic abscess in the back and a fœtid bronchitis. He had also an abscess in the base of the right lung which he was able to empty per mouth each morning the expectoration being very offensive A few tubercle bacilli were found in the sputum. Dr Callender endeavoured to strike the abscess in the lung with an aspirating needle without success, however as regards reaching the abscess, but a pneumothorax developed and this, Dr Callender presumed by making the lung contract helped to obliterate the abscess cavity and also gave the lung rest. The patient expressed himself as feeling much better after the pneumothorax appeared the amount of expectoration became much less and not so fœtid. An abscess formed in the wound in the neck which healed after being freely opened. Seven weeks after the operation on the lateral sinus the patient got a letter for admission to St. Mary's Hospital London where he was kept for a short time, and after being at a convalescent home at Ramsgate for a month he returned home in good health and able to resume his work. The facial nerve was unfortunately damaged and has not recovered its function though improvement is apparent.

---

[1] Jacobson and Steward: Operations of Surgery, fourth edition, vol. i p 256

Remarks by Dr CALLENDER.—There are several points of interest in the case 1. The few subjective symptoms the patient never complained of pain in the head or neck. There was stiffness of the neck but no pain or tenderness. 2. Persistence of rigors and high temperature after the mastoid had been freely opened made the diagnosis of lateral sinus mischief probable. 3. The foul breath and expectoration pointed to pyæmic pulmonary complications though at first, there being absence of physical signs in the lungs, it was thought that the foulness of the breath might be due to pus from the Eustachian tubes. 4 The improvement of the pulmonary abscess after pneumothorax had been produced was interesting

Reviews and Notices of Books

The Diseases of Children. By JAMES FREDERICK GOODHART M.D Aberd. with the assistance of GEORGE FREDERICK STILL, M.D Cantab. Seventh edition. London J & A. Churchill. 1902. Pp 813. Price 12s. 6d

THE preparation of the seventh edition of Goodhart's "Diseases of Children" has evidently entailed a very considerable amount of revision certain sections have, indeed, been almost completely rewritten. Among the subjects which are now added for the first time or which are so completely remodelled as almost to defy recognition those which deal with the feeding of infants, with the diseases of the nervous system, with hypertrophic pyloric stenosis, and with achondroplasia are perhaps the most important. The chapter on rheumatism has also in several notable respects been subjected to the process of revision with the result that it constitutes one of the most interesting and enlightened chapters in the book. However we do not feel altogether convinced that a student will gain such a clear clinical picture of what Dr Goodhart calls the composite of the disease as he would do had he to rely for his instruction on any one of the former editions. To draw a clear line of demarcation between the 'status rheumaticus and acute rheumatism has strained the intellectual resources of other authors besides Dr. Goodhart and Dr Still, and it is instructive to follow the ingenious generalisations and circumlocutory processes whereby all direct solutions of the problem are shelved or evaded. Children," we are told, do indeed suffer from typical acute rheumatism with its fever its pain, its swellings of the joints its sweating but to circumscribe it (i.e. the term rheumatism) by these limit would be to ignore the larger part of the field of its workings" For the purposes of establishing a diagnosis it is suggested that we should rely on the family history and a record of small and insignificant ailments. Growing pains, skin lesions, nervous irritability, and anæmia—in fact, the same group of symptoms which certain authorities, and notably French writers, refer to the arthritic diathesis—are the hereditary conditions which, according to the authors, constitute the status rheumaticus, and they are to be ascribed to certain inherent faults of the nervous system and to certain disabilities of nutrition. The authors admit, indeed, that the pathology of rheumatism is still a much vexed question and proceed to explain that of late evidence has been collecting which would seem to show that it may possibly be of microbic origin." We may be quite wrong in the assumption but after carefully reading this chapter on rheumatism we cannot help thinking that Dr Goodhart and Dr Still are not in absolute agreement on its essential pathology and that there have been mutual antagonisms as there have been mutual concessions. At all events, there are indications of a distinct disinclination on the part of the writers, metaphorically speaking to burn one set of boats behind them and to abandon the neurotrophic diathesis before adequate transport of a bacteriological character has been provided there is, in fact a tendency to halt between two opinions.

In the chapter on tuberculosis the authors incline to the belief that infection in infancy is chiefly by way of the respiratory tract without denying that the germs of tuberculosis do occur in milk they do not regard milk as a frequent medium of infection However it must be remembered that the lungs can become infected through other channels than through the air-passages and whether lungs or bowel become demonstrably infected may be merely a question of local resistance. The alimentary tract must indeed be endowed with considerable power of resistance or from the swallowing of sputum it would almost invariably become infected in all cases of pulmonary tuberculosis. We do not think that, as far as tuberculosis is concerned the authors have established their case against milk infection or indeed, against infection generally by way of the gastro-intestinal tract.

The chapter on the feeding of infants, especially with reference to that part of it which concerns the preparation of milk mixtures, is, in our opinion, altogether inadequate and, in view of the importance of the subject, it is disproportionately short. Moreover nearly a page of valuable space is taken up by a table which is quite useless as it stands, without instructions as to how to employ it. This table, which appears on page 47 gives in detail the percentage composition of milk suitable for the various ages of infancy and it might just as well have been omitted

We are glad to notice that the vigorous and refreshing style which rendered former editions of the work such pleasant reading still retains its directness of expression Although in his preface Dr. Goodhart says he gladly remits to Dr Still the chief responsibility for the additions and improvements," it is clear that the latter has found some difficulty in overcoming the literary troubles of dual authorship. For instance, there is no consistency in the use of the first person singular or of the first person plural and it is difficult in places to understand whether I" means I Dr Goodhart, or I Dr Still just as there is ambiguity about the meaning of the we's. We do not know which author is responsible for them but we cannot help drawing attention to the following sentences and asking for a literal and literary interpretation The life of the child is balancing" (p 433) and I think that rheumatism taints more than an average of such." Again, we would ask how a new born infant can sit up (p. 21) or how it is that the healthiest children" are liable to show symptoms of infantile paralysis (p. 527) Might not also the frequent references to the late Dr Sturges indicate in some way or other that this lamented physician is no longer with us! To be still further critical we would call attention to formula 45 on p 784 It would pass the understanding of most druggists to dispense this medicine Ingredients which in themselves total three ounces and one drachm cannot by the addition of water be made up to three ounces only In the treatment of chronic constipation in childhood the continued use of enemata and glycerine suppositories is favourably regarded For our part we regard these therapeutic procedures as most objectionable A rectum is a good rectum or a bad rectum according as its capacity for expelling its contents is physiologically normal or the reverse. If the rectum is to be trifled with by nurses using enemas and glycerine suppositories indiscriminately how can it retain its delicate sensitiveness or its powers of expulsion ?

In reviewing a book so well known and so highly appreciated as Goodhart's "Diseases of Childhood" we feel confident we can in no way detract from its well recognised merit by recording the few blemishes which a thorough and careful reading has divulged. We can, we believe, bestow no higher praise than by saying that this last edition is in all important respects superior to any of its predecessors

---

Diseases of the Organs of Respiration. By SAMUEL WEST, M A., M D Oxon, F R.C P Lond., Assistant Physician and Lecturer on the Principles and Practice of Medicine at St. Bartholomew's Hospital, Senior Physician, Royal Free Hospital, Consulting Physician to the New Hospital for Women, formerly Physician to the City of London Hospital for Diseases of the Chest, &c. In two vols With numerous Diagrams and Illustrations London Charles Griffin and Co 1902. Vol. I, pp 398, Vol. II., pp 399–913. Price 36s

THE fuller description on the title page informs the reader that this work is "a treatise on the etiology, pathology, symptoms, diagnosis, prognosis, and treatment of diseases of the lungs and air-passages" The book is divided into sections and not chapters and the relative importance of its parts is indicated by types of different kinds We agree with the author that such an arrangement renders reading and reference easier It does not, however, follow that those sections which stand in small type are of little importance, they are in many cases, as in the article on Pleural Tension, of special rather than of general interest. The satisfactory plan of printing the report of clinical cases in small type is also adopted and the same type is used with matter which is added to illustrate or to explain the conclusions stated in the text.

The "introductory" section deals with the anatomy of the lungs and the physical examination of the chest. Dr West makes some interesting remarks on two points in connexion with auscultation of the chest. All physicians connected with teaching hospitals realise the difficulties experienced by students in learning the "physical signs" connected with diseases of the lungs This is in great measure due to the confusion of terms adopted by various writers Some authorities use the words "bronchial," "tubular," and "cavernous" as applied to breath sounds as synonymous terms while others impart to them differences as regards signification which they scarcely possess The real confusion is however, not in facts but in words If physicians would determine a definite nomenclature the difficulty would be lessened. Dr West attempts to describe in words the various varieties of breath sounds and adventitious sounds This is a difficult task, but he has succeeded well He has, however, omitted one point which is of considerable importance—namely, the comparative pitch of inspiration and expiration To those practitioners who possess a musical ear the observation of alteration in pitch of expiration (more particularly) is of great service in determining the variety of breath sounds. Dr West also dwells on a second term which is a source of confusion—namely, "râles." The student who carefully studies the author's remarks will derive a clear idea of the nature and signification of adventitious sounds

The diseases of the air-passages are next discussed and a comprehensive account is given of "respiratory obstruction." The classification of causes of obstruction to the air-tubes is both complete and practical

We recommend Dr West's remarks on the serum treatment of diphtheria to those who are not even yet convinced of the immense utility of the antitoxin injections He rightly insists that in every case of diphtheria where laryngeal symptoms are present, whether pronounced or not, the serum treatment should be commenced without a moment's delay, for the success of the measure depends largely upon its being commenced in good time.

The sections on bronchitis, empyema, and bronchiectasis are all well written and thoroughly up to date The student will also find useful information in the section dealing with "hyperæmia, congestion, hypostatic congestion and œdema" of the lungs. These terms are frequently misapplied and therefore likely to lead to confusion The remarks on the "bacteriology of pneumonia" will also attract attention. After a brief historical review of the subject Dr West concludes that though the pneumococcus is the pathogenic organism of the ordinary or idiopathic croupous pneumonia many other organisms also can excite an acute inflammatory infection of the lung, which so far we have no clinical means of distinguishing from pneumococcus pneumonia—e g, the pneumo-bacillus, streptococcus pyogenes, staphylococcus pyogenes aureus, bacillus tuberculosis, bacillus anthracis, and possibly many others We agree with the suggestion that perhaps the peculiar course which many cases of pneumonia run may depend upon the nature of the infecting germ or upon some mixed infection, and some day it may be possible to recognise these different forms of pneumonia by their clinical signs, but at present science has not progressed so far

One of the most interesting sections in the first volume is that on broncho-pneumonia. Dr West maintains that there are three clinical varieties of broncho pneumonia (1) that in which the disease is of gradual onset and preceded by some affection of the air-tubes, the course prolonged and interrupted by frequent relapses, and the termination by lysis, (2) that in which the history and symptoms are similar but the disease is of sudden rather than of gradual onset, and (3) that in which there is no antecedent affection of the air-tubes, the affection is of sudden onset and short duration, the termination is by crisis, the clinical symptoms are, in fact, those of croupous pneumonia but the lesions those of broncho-pneumonia. In other words, the secondary and primary broncho-pneumonias are clinically and pathologically different diseases, and while the secondary stands in close relation with bronchitis and similar affections of the air tubes the primary stands in close relation with lobar pneumonia. In order to prove these contentions Dr West examines closely the work which has been accomplished in regard to the bacteriology of broncho pneumonia Without entering into detail on this point we give the conclusions to which the evidence adduced points The primary and secondary broncho-pneumonias are shown to have a different bacteriological origin. Secondary broncho-pneumonia is for the most part due to streptococcus infection, derived from some source connected with the air tubes, throat, or mouth It is further shown that primary broncho-pneumonia is of pneumococcal origin and that pneumococcus inflammation occurs with almost equal frequency in the child and in the adult. This second fact is not generally recognised, there being a general opinion (now shown to be erroneous) that the pneumococcal inflammation is much more common in adults than in children The inflammation however, takes a different form in each—in the adult producing massive consolidation and in the child disseminated patches of consolidation These remarks merit most careful consideration, for if the conclusions prove correct the term broncho-pneumonia must be reserved for those affections of the lung which follow antecedent affections of the bronchi and must not include the idiopathic forms

Volume II. commences with the subject of phthisis." We are somewhat doubtful whether Dr West has acted wisely in retaining this term. Pulmonary tuberculosis" is more exact and more scientific Dr West defines phthisis as a specific disease caused by the tubercle bacillus," and adds, It *is the commonest form of tuberculosis of the lungs*, though not the only form. Phthisis simply means wasting Some authorities still maintain that there are destructive diseases of the lungs which can neither be recognised as tuberculous nor referred to any other well known group, for such ' phthisis pulmonalis may for the present be the most appropriate name. By adopting the term pulmonary tuberculosis" the nomenclature of tuberculous affections is more brought into line, tuberculous meningitis and tuberculous peritonitis are terms universally employed and we think that Dr West would have done better service to nosology by heading the section pulmonary tuberculosis than by retaining the ancient and unscientific term ' phthisis.

The description of the pathology and etiology of the disease is excellent, as is also the clinical consideration. The remarks on treatment, too are thoroughly in accord with modern ideas. We are quite in accord with the remarks on climate, especially do we support the contention that the English climate frequently seems to fail because *patients are left too* much to themselves and for the want of institutions where rules must be kept, live in their own lodgings or hotels, do much as fancy leads them and are often most imprudent.

The sections on affections of the pleura will be read with considerable interest. Dr West s views on intra pleural pressure, more particularly in connexion with pneumothorax and serous effusion are *well known and the reader* will find them fully discussed in this volume. The account of the clinical phenomena observed in cases of pleuritic effusion is also excellent. We are glad to observe the author's views on washing out the pleura after the pus has been evacuated in cases of empyema. Washing out the pleura is often objected to as being a risky or even dangerous operation We agree with Dr West that this is not the case. It is quite true that disastrous cases have been recorded and have been attributed actually to the washing out Most of these cases have been instances of sudden death but it must be remembered that death may take place suddenly in cases of pleural effusions in which the pleura has not been washed out and has not been even incised. The usual precautions must, of course, be *taken to* be sure that the fluid is warm and the vent free so that the fluid may flow out readily Some surgeons prefer to swab out the pleura and this procedure may be adopted without fear of danger The volume concludes with descriptions of the rarer affections of the lungs, such as syphilis actinomycosis, pneumonomycosis, hydatid disease, and new growths of the lungs and pleura.

In conclusion we can speak in the highest terms of praise of the whole work. It will be found useful both by the practitioner and by the student and we can confidently recommend a perusal of it to our readers.

Trades Waste its Treatment and Utilisation. By W NAYLOR, F C S A.M.I.C.E With 21 Plates 27 folding Diagrams and numerous Illustrations in the text. London Charles Griffin and Co 1902. Pp. 267 Price 21s.

THE prosperity of a country may be fairly gauged by its trades waste, but unfortunately trades waste is generally synonymous with the pollution of rivers It cannot be gainsaid however, that great improvement has been made during recent years in regard to the prevention of the pollution of rivers and for this desirable state of things we have mainly to thank the Rivers Pollution Commission which was appointed in the year 1867 This Commission found that the rivers were grossly polluted and it pointed out that a good deal of this pollution could be stopped and that there was no reason why it should not be stopped Admirable, however, as the provisions of the Act may have been it is the fact that those possessing powers under this Act have not exercised them with that assiduity which in such a *case was very desirable.* Luckily however officials have been appointed to watch over the possibility of offence being committed who, zealous for the purity of our streams and for the public health have compelled the manufacturer to adopt some means of preventing outrage on the purity of the stream. It is satisfactory to be able to record year by year however that waste is a diminishing factor appearing elsewhere as valuable material. *One remarkable example* is that of alkali waste For years alkali manufacturers could do nothing with the residue from the manufacture of alkali by the Leblanc process but to dump it down in waste places until the accumulation was such that the works became surrounded by small mountains of the waste. By Mr Chance s process this waste is now made to yield sulphur in a pure state and an inoffensive material is left instead of one which was most offensive and which yielded a poisonous yellow liquor that not infrequently found its way into rivers.

The book before us gives a number of interesting examples of the difficulties met with in dealing with trades waste and of the methods employed in the various trades to overcome these difficulties. The work is essentially one for the chemical engineer but it is also of great interest to the economist and to the sanitarian It is written by one who possesses great practical experience of the pollution of rivers and of the practicable means that can be adopted for its prevention. Probably Lancashire as a polluting area has been a most difficult tract to deal with. The Manchester Ship Canal though less offensive than it used to be, is as black as ink, and the Ribble and Mersey have been notoriously maltreated by manufacturers Mr Naylor is the chief inspector of rivers to the Ribble joint committee and therefore he must have been face to face with some of the worst trade problems offered for solution, indeed it is obvious from a perusal of his book that the field which he has explored is a wide one. The subjects treated comprise woollen mill waste, waste from tanning and fellmongery brewery and distillery waste, waste from calico bleaching dyeing, and printing papermaking waste, and general chemical waste. Special processes of purification are fully illustrated

We *regard* this book as a contribution of considerable importance not merely because it will prove a valuable and instructive guide to borough engineer surveyors analysts, and others, but because in setting forth clearly the causes of the pollution of rivers and the best known practical means of preventing such pollution it is calculated to assist in the attainment of a much better state of things an end which is *of* the utmost concern to the whole country

---

Gibson and Russell's Physical Diagnosis. Third Edition Revised and Rewritten by FRANCIS D BOYD C.M G M D F R.C.P Edin Assistant Physician Edinburgh Royal Infirmary Physician to the Deaconess Hospital. Edinburgh and London Young J Pentland 1902. Pp. 448.

THE third edition of *this excellent* manual has been revised, and in great part rewritten, so as to bring it up to the requirement of modern medicine. Several new sections have been added describing in detail new or improved methods employed as an aid to diagnosis Many of these are now fully recognised and may be made use of either in the ordinary routine of practice or in the investigation of unusual cases of disease

The chapter on the Examination of the Blood contains the results of the investigations which have recently been made in the pathology of the blood It is now well recognised that a clinical examination of the blood is of the highest importance and will frequently afford considerable help in the elucidation of cases of doubtful diagnosis The manner of obtaining the blood for examination is described as are the various methods which are employed in fixing and staining the films The processes which were formerly employed to demonstrate the varieties of the white blood corpuscles were clumsy and intricate and required a long time for their completion Now, however, the films may be rendered ready for examination in a few minutes and with a little practice may be satisfactorily employed in ordinary professional work

Another method of clinical investigation has lately been much used, especially on the continent—namely, the investigation of the contents of the stomach. This procedure has not been largely adopted in this country owing probably to the discomfort experienced by the patient in the frequent passage of the stomach tube Nevertheless, in certain cases valuable information may be derived by administering a "test meal," and then after an interval drawing off the contents of the stomach and submitting them to examination In the volume now before us brief but explicit directions are given as to the carrying out of the necessary operations.

A section has also been added on Intestinal Parasites. Directions are not given, however, as to the examination of the stools for the ova of the parasites, unless the dejecta are suitably treated these bodies will very probably be missed.

The section on the Cranial Nerves will also prove a valuable addition to the book. The description of the phenomena produced by paralysis of these nerves is clear and lucid. The symptoms are detailed in comparatively few words so that the practitioner will find this section very handy for the purposes of reference.

A short chapter is devoted to the subject of Clinical Bacteriology It seems needless to state that the important position which bacteriology now takes in medicine renders a certain knowledge of the methods employed in diagnosis essential to the physician The isolation and recognition of micro organisms are, it is true, necessarily carried out in the laboratory by an expert, but the student should know how to obtain material for examination, how to examine the material when obtained, and how to stain and to recognise the commoner pathogenic organisms The author wisely refrains from attempting to give a complete description of the many processes now employed in clinical work, but those more frequently required are explained The examination of the sputum for micro-organisms is well described and a few remarks are made on the examination of the products of inflammatory exudation

The practitioner and student will find this volume very useful for reference and study when engaged in clinical work.

Rhinology, Laryngology, and Otology and their Significance in General Medicine By E P FRIEDRICH, M.D, *Privat-docent* at the University of Leipsic Authorised translation from the German. Edited by H. HOLBROOK CURTIS, M D, Consulting Surgeon to the New York Nose and Throat Hospital and to the Diphtheria and Scarlet Fever Hospitals Philadelphia and London W B Saunders and Co 1900 Pp 348 Price 10s

DR FRIEDRICH in his preface makes the pertinent remark that a speciality should not be regarded as a thing apart and a kind of appendage, but that it should take an active part in all problems in the solution of which general medicine is concerned, to do which active coöperation between general medicine and the various specialities is indispensable, and that, should this be lacking, a speciality runs the danger of becoming a mere source of revenue and of losing its scientific interest. He considers the influence of diseases of the nose, throat, and ear with those of the respiratory organs, of the circulatory system, of the digestive system, and of the blood, with constitutional diseases, with infectious diseases, acute and chronic, with diseases of the kidney, with diseases of the skin and of the sexual organs, with diseases of the eye, with intoxications, and, lastly, with diseases of the nervous system, to which he adds an appendix dealing with nasal reflex neurosis, the significance of some of the cranial nerves, and diseases of the meninges and cerebral sinuses in rhinology and otology

Dr Friedrich, in examining the relationship existing between the nose, pharynx, and larynx, and between them and the lungs, alludes to the most interesting experiments made by Paulson and others as to the respiratory pathways of the nose, with whose views he expresses a thorough concurrence, concluding that we are quite justified in assuming that the respiratory current passes principally through the middle and lower parts of the nose and hardly touches the interior meatus in normal conditions Whilst discussing the action of the nasal mucosa Dr Friedrich considers that at present we do not possess sufficiently exact proof to say more than that the nasal mucosa is not a favourable soil for the development of micro organisms and that it does, more or less, hinder their development He also incidentally remarks that the larynx is not entirely occluded during deglutition by the epiglottis and that the bolus of food glides easily into the œsophagus from the arched dorsum of the tongue, which guards the entrance of the larynx, an observation which is not devoid of significance with regard to that moot point, the function of the epiglottis As regards the question of the connexion between diseases of the lungs and morbid conditions of the upper air passages he favours the views of Störk and Sticker that fœtid atrophic rhinitis in all probability bears more than a casual relationship with syphilis, that in patients suffering from this disease there is a general xerosis of the mucous membranes of the respiratory tract, and that the tendency to a dry catarrhal condition extends into the smaller bronchi. The author states that the most frequent complication of lung disease in the larynx consists of paralysis, a statement which is open to question, considering Kidd's estimate that 50 per cent. of all tuberculous patients suffer from a secondary laryngeal infection, though apart from this the statement is correct. In discussing the effects of disturbances of the normal functions of the Eustachian tube due to alterations in the upper air passages Dr Friedrich very truly says that the various views advanced by text-books on the conditions found in disease of the middle ear, whether due to a chronic catarrhal middle-ear inflammation or to middle ear disturbance by obstruction of the Eustachian tube, have never clearly differentiated between these two conditions, and have, in fact, only tended more to confuse matters

The author carefully analyses the various opposing theories regarding the paralysis of the recurrent nerve, and after a very fair and impartial statement thoroughly endorses Semon's theory In discussing secondary infection of the larynx in cases of tuberculosis of the lungs he expresses himself in the following terms 'In view of our clinical and anatomical experience, we recognise infection of the larynx by way of the lymph channel as probably more frequent and reserve infection by contact for those cases which manifest themselves in the form of erosion ulcers ' This definite expression is particularly valuable in view of the tendency to consider infection by contact the more usual mode of infection in this disease.

Dr Friedrich has presented the profession with a work of great interest, the value of which will be acknowledged by all scientific students of medicine The book has lost nothing in the translation, for the language is clear and the translator has freed himself entirely from any tendency to *adhere to German construction.* Dr Friedrich has a wide knowledge of diseases of the nose, throat, and ear besides being a good general physician, and his readers cannot fail to appreciate the close reasoning that he exhibits. His book will, we trust, find its way into the hands of both general physicians and specialists in diseases of the throat, nose, and ear, for they will find much in it which will prove of value and much which is placed in a new light. We may safely say that no one can read the book without deriving a large amount of intellectual pleasure as well as extremely valuable information

LIBRARY TABLE.

The Method of Cuignet or Retinoscopy By E H. LENDON M A. M.D Oxon London Baillière Tindall and Cox. 1902. Two volumes crown quarto Pp 66 in the first volume , 52 in the second volume. Price 10*s* 6*d* —The first of these volumes contains some 66 pages of letter press describing in wearisome detail the well known method of retinoscopy We cannot agree with the author that the theory of the subject is either complicated or difficult. It is fairly well described in most of the text-books on refraction and ophthalmology Sir William Bowman used this method to discover regular astigmatism some 14 years before the publication of Dr Cuignet s paper on Keratoscopie in 1873. It is to Dr Parent s contribution in 1880 that we owe our first true explanation of the phenomenon so that the very title seems open to criticism. We should expect in a work devoted entirely to this subject to find extreme accuracy in the details, but this is far from being the case. The author for instance, says that if a concave mirror is used of 25 centimetres focal length and a lamp is placed 120 centimetres from it, a real inverted image of the lamp is formed at about 30 centimetres distance. It would really be formed at a distance of *more than 31¼ centimetres* The second volume is merely an atlas of 13 diagrams of the familiar principles of retinoscopy their purpose would have *been amply served by two figures incorporated* in the text. With reference to the notation of the angles at which cylinders should be set, Dr Lendon says By far the best way is to have two nasal zeros, as in Fig 13 " The standard notation in which 30° indicates that the right end of the axis is raised 30° from the horizontal is far preferable, for no further specification is then required and it is in complete accordance with the notation that is universally accepted in mathematics. We *have nothing* but praise to give for the printing paper and binding of these somewhat unnecessary volumes

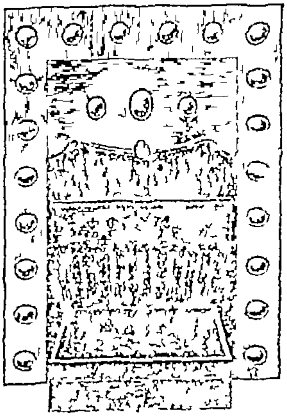
The Key to Sight testing By H. L. TAYLOR and W S. BAXTER. Birmingham J and H. Taylor 1902. Pp. 355. Price 6*s* —This book is written by practical opticians for the use of opticians and not of ophthalmic surgeons. It is divided into three sections, the first dealing cursorily with the Eye as an Optical Instrument, *its physiology and even* with its pathology We fail to see what an optician has to do with ocular affections peculiar to anæmia, diabetes, gout, kidney and brain *disease.* These few affections are taken at random from the 20 diseases dismissed in as many paragraphs. We note, however that syphilis is not mentioned. The book would be more useful to the optician if more information were given about the optics that are daily required by the working spectaclemaker instead of confusing him with using the same symbol (D) to denote the curvature of a lens and its refractive power in dioptres. The second section is on the Testing room and on the recognition of ametropia, heterophoria, and other points which are the special subjects of the ophthalmic surgeon This section describes well the use of the pinhole diaphragm, the stenopaic slit, the ophthalmometer and the case of trial lenses. The method of retinoscopy is shortly but fairly well described, but we must protest against opticians using the ophthalmoscope to recognise optic neuritis optic atrophy choroiditis, and hæmorrhages even if such observations are ' mentioned to the oculist taking the case over ' Five pages are devoted to the use of the perimeter and four and a half to ophthalmoscopy the reader being referred to Haab's Atlas of Ophthalmoscopy for further information. *The third section is on the Workshop and deals with* spectacle-frames and the tools and appliances required for fitting them. This section appears to be good and we note with pleasure the strong recommendation of the standard notation for the determination of the angle at which the axis of a cylinder should be set This is one in which the angles are measured *in both eyes in the counter clockwise* or positive direction from the horizontal meridian.

New Inventions

THE WESTMINSTER ECONOMIC STOVE.

MOST stoves intended to bring about the complete consumption of coal, that is, without the production of smoke, involve alterations in the ordinary domestic heating methods to such an extent as to put them beyond the bounds of practical application. By the arrangement suggested in the Westminster Economic Stove, however *the change does* not require any severe structural alteration. The efficiency of the stove is patent from the fact that by its means even refractory anthracite or coke may be lighted just as quickly as ordinary bituminous coal. In fact, the stove *has been designed* essentially for burning smokeless fuel, although by its construction the formation of smoke from smoky coal is decidedly minimised. A glance at Fig 1 will explain the principle upon which the successful working of the stove *depends. Instead of a fixed*

FIG 1



Stove with the fire grate up.

grate a pivoted movable one is adopted, which may be lifted up at a little less than a right angle with the ash-pit at a point quite close to the dome at the top In this position it is obvious that the whole of the air supply must pass through the bars and through the fuel. That is to say, at lighting there can be practically little air passing up the chimney which is not concerned in the combustion of the fuel The result is a powerful draught which soon produces a sort of blow pipe flame which will readily ignite anthracite or coke, while in the case of coal the air is so heated that the combustion is very effective The lighting of the fuel occurs with great rapidity As soon as the active combustion of the fuel is established the grating may be lowered to its ordinary position over the ash tray The stove works with a decided economy and with a minimum production of smoke and soot, as is easily observed from the state of the chimney after the stove has been in use for some time. The appearance of the stove with the fuel alight is shown in Fig 2. Certainly the stove is very powerful in producing radiant heat—a fact which shows that the combustion is active and not sluggish, in spite of which the consumption of fuel is distinctly economical The Westminster Economic Stove is the invention and property of Messrs Bostel and Sons of Ebury-street, London, S W

Royal Edinburgh Hospital for Sick Children —The forty third annual report of the Royal Edinburgh Hospital for Sick Children states that during the year ending December, 1901, 1616 cases were treated in the wards and 7015 out-patients attended at the dispensary The surgical operations numbered 1434 The financial report shows a large deficiency in the ordinary income, but notwithstanding an increase in the number of patients treated during the year the expenditure has fallen The directors are gratified to notice that there is a growing interest taken in the hospital by Sunday scholars a sum of over £129 having been collected in Sunday schools for the charity

Donations and Bequests —The late Mr W H Loder of High Beeches, Handcross, Sussex, bequeathed £1000 to the Cheyne Hospital for Children for the endowment of a "Winifred Cot" which had been previously maintained by Mr Loder and his wife, and £500 to the Sussex County Hospital.—Under the will of the late Mr H. K. Hebb of Lincoln £500 are bequeathed to Lincoln Hospital and £50 each to the Lincoln General Dispensary, the Mabelthorpe Convalescent Home, and the Royal Bath Hospital at Harrogate The *Hertford Infirmary* benefits by a sum of £200 under the will of Mr A. P MacMullen of Hertford.

THE THAMES CONSERVANCY

The general report of the proceedings of the Conservators of the River Thames for the year 1901 shows that they have carried out an enormous amount of useful work The chief part of the funds at their disposal is spent on the lower river but the amount of money at their command is quite inadequate for the execution of all the work which ought to be done During the last year some unusual expenses had to be incurred in connexion with the Royal Commission on the Port of London It may be hoped that the recommendations given in the Commissioners' report will be so far adopted as to ensure that the Port of London shall not lose all its trade, and it is perfectly obvious that the Conservators of the Thames have never been able to carry out the work they thought necessary because they have always been hampered by want of money Amongst the various duties of the Conservators the purification of the upper river, however, is the only question with which it is incumbent upon us to deal from a sanitary point of view Under the Thames Act of 1894 the powers of the Conservators in regard to river pollution were extended to embrace the whole of the Thames watershed above the western limits of the metropolis In carrying out their duties, as most riparian owners and as all the local sanitary authorities know, the Conservators have been most persistent, but they have never taken legal action unless and until it was quite evident that no attempt was, or was likely to be, made to remove an existing cause of pollution The inspecting staff of the board constantly visit all the centres of population within the area which is under their supervision and the sewage effluents which discharge into the river are frequently analysed During the year 1901 26 towns and villages diverted the pollutions with which they had previously defiled the water, and amongst these places were Cranleigh and Woking, Wendover and Thame, Newbury and Hemel Hempstead At some other towns the requirements of the Conservators have not yet been complied with, and amongst these are Witney, Chipping Norton, Marlborough, Kingsclere Rickmansworth, West Drayton, and Leatherhead , but in most cases steps are being taken to effect improvements In some places nothing was done because difficulties supervened in regard to the acquisition of land for the purpose of sewage disposal. At Amersham, Watlington, and Hungerford the local authorities have at length reached the stage at which "schemes" are proposed. The Aylesbury sewage effluent has been improved During the year legal proceedings against peccant local authorities and individuals have been taken in only 11 cases. In two instances the persons summoned thought it wise at once to comply with the Act and in six other cases they promised to do so In a large number of instances (263 in all) pollution has been diverted from factories, farms, and private houses. The inspection of house boats and launches on the Thames has been regularly carried out with a view to ensure that the sanitary arrangements on board are in a satisfactory condition Considerable improvement has been effected in this respect since attention was first prominently called to the matter in the columns of The Lancet some years ago

There is still an important matter over which the Conservators at present have no control, the absence of which is a distinct flaw in the Conservancy Act of 1894 At any distance greater than three miles from the Thames they have no authority to enable them to prevent the passage of trade refuse into the streams The Conservators suggest in their report that their general powers for preventing these pollutions above the metropolis should extend over the whole of the watershed without limitation. We entirely agree with this recommendation.

The Thames Conservators have constantly carried out their duties with efficiency, with tact, and with economy They have never wasted the money entrusted to them in vexatious litigation No public body possessing sanitary control in this country has ever done anything like so great a work with so little fuss and with such constant care They may safely be entrusted with the increase of power for which they ask , it is indeed evident that the purity of the Thames cannot be effected whilst trade pollutions are permitted to defile the waters of its tributaries

THE LANCET.

LONDON SATURDAY SEPTEMBER 20, 1902

Virchow as Pathologist

IN estimating the influence of VIRCHOW'S work on the evolution of contemporary pathology and in appraising the practical value of his labours in the interpretation of *disease it would be unjust to his genius to enumerate* merely the roll of his positive achievements. His victories lay rather in his fearless exposure of the many false premisses and conceptions which obscured and paralysed the progress of medical knowledge, in redeeming from all suggestion of mysticism our understanding of the essential processes of disease, and in establishing for all time on the firm basis of truth the principles which should guide us in every biological inquiry In organic evolution it is ever interesting to hazard a speculation as to what might have been the ultimate term of any particular series had any one of the factors in the chain of events which produced such a series been different in kind or in degree. What, for instance would have eventuated in the evolution of the animal series had there been no glacial period? or what would have been the ultimate effect on the development of man had some great upheaval of nature destroyed our first vertebrate ancestor without giving him an opportunity of stamping his individuality upon succeeding generations? And in like manner the speculation is not without interest to consider what would have been the trend of evolution in pathology had not VIRCHOW arisen with almost superhuman omniscience to knit together the tangled threads of divergent opinion into a homogeneous fabric of rational medicine? Would progress have advanced along the discordant lines of humoral pathology? would the embittered strife of opposing schools still sap the energy of giants and direct the stream of genius into profitless and barren channels? should we still be seeking for the essence of disease in the Archæus of PARACELSUS? and would the grosser problems of pathology still remain unsolved, tarrying for the unfolding of the secrets of life? However without indulging further in vain speculations as to the possible fate of present-day pathology had not the genius of VIRCHOW indicated the path which leads to the haven of truth we will proceed at once to a consideration of the positive results of his investigations and arguments and of his influence in the determination of the universal theory of disease which to-day is accepted in every quarter of the civilised world

Concisely stated, this theory is that all disease presupposes life and that life is the property of the cell The activities of the cell are the expression of this life, and they are evoked by stimuli of various kinds which reach the cell from without. The activities of cells individually or collectively are called physiological or normal as long as the general equilibrium of the organism is not disturbed They become pathological when they overstep this limit. The conception of the identity in kind of these two vital processes—physiology and pathology—we owe largely to VIRCHOW His discovery that all animal tissues which gave physiological or pathological evidences of life were composed of individual cells which responded to stimulation made it possible to apply this universal law of disease to every organ or structure in the body He proved with the inadequate means at his disposal that bones and cartilage and connective *tissue were anatomically constructed* on the same cellular plan which applied in the case of muscles or secretory glands. He further showed that under the influence of appropriate stimuli each individual cell was capable of dividing and becoming two, and thus he not only explained growth regeneration of tissue and tumour formation but, to use his own words, he was in a position to give utterance to the dictum, *Omnis cellula e cellulâ* and to close the great gap which HARVEY'S Ovistic theory had left in the history of animal organisation. The far reaching applications of this great truth were probably hardly realised by VIRCHOW at the time when he formulated his immortal aphorism and it is possibly *no hyperbole of speech* to say that even to-day its significance to a considerable number of minds is little more than a denial of the possibility of spontaneous generation. The conception of disease as a process and not as an entity is founded on a recognition of the law that cells respond to stimuli by the manifestation and transformation of energy and there is no branch of medicine or pathology which has not been profoundly affected by the application of this general principle. We can recognise in the protean symptoms of syphilis the consequences of cell excitation *due to the circulation* of some intangible poison which we cannot isolate and which we have never seen, but which by the particular application of VIRCHOW'S teaching we know must exist. We can recognise in tuberculosis the effects of constitutional poisoning and the formation of granulations and cells of distinct morphological structure due to the presence of living and organised stimuli which indirectly he *has enabled us to* isolate, recognise, and define. The insistence on the part of VIRCHOW that specific stimuli produced specific results that the character of the pathological *lesions* are dependent on the specificity of the stimuli—that is to say on the qualitative rather than on the quantitative properties of the irritant—brought him into direct antagonism with HUEPPE and his school and exposed him to the satirical eloquence of that philosopher and bacteriologist. The study of the life-history of bacteria as occasional causative agents in the production of disease is a comparatively new albeit a highly fruitful, line of research which in the light of VIRCHOW'S cellular pathology has been opened up and placed upon a rational basis. It is perhaps not too much to say that the development of our knowledge with regard to immunity to the formation of toxins and antitoxins is founded on principles which have been directly evolved from the fundamental conception that the cells in the animal body react mechanically and chemically to foreign stimuli. On no other physiological basis could their significance be intelligible or the part which they play in the determination of disease be logically explained

In 1858, when VIRCHOW published his "Cellular Pathology," the work, for which his memory will be for ever immortal, was in a sense complete, and it is a curious coincidence that another work, which won its author everlasting fame and was also in itself almost a complete system of biology—namely, DARWIN'S "Origin of Species" —was likewise published about the same time. VIRCHOW, like DARWIN, sprang into fame with startling suddenness, both of them commenced their illustrious careers by propounding a unitary theory of life which revolutionised their respective departments of biology, and both of them spent the rest of their lives in substantiating details which, though of individual value and interest, were almost entirely of secondary and subsidiary importance in comparison to the limitless possibilities of the great arguments which were outlined and unfolded in these monumental volumes The record of VIRCHOW'S published writings has probably never been equalled by any other scientific investigator The mere titles of his contributions to pathology, quite apart from other subjects, fill more than 20 pages of SCHWALBE'S closely written bibliography, a volume which was published to commemorate the veteran pathologist's eightieth birthday and which was a complete record of all his published works Among the more important results of these prolific labours must be included his early investigations into the conditions of vascular inflammation and the refutation of the then accepted theory of phlebitis, while our knowledge of embolism owes its origin and a large measure of its further development to his histological and experimental researches. In this connexion it is interesting to note that PAGET, to whom VIRCHOW undoubtedly owed certain inspirations for his "Cellular Pathology," should have noticed the same morbid changes in various forms of embolism which VIRCHOW subsequently described and to which he attached a true pathological significance. He further indicated the difference between leukæmia and pyæmia and paved the way for the brilliant results which have more recently been achieved in the differential diagnosis of kindred conditions by the finer methods of hæmatology We further enjoy the fruits of his labours in a better understanding of the puerperal condition, of animal pigments, of lardaceous disease, of trichiniasis, of syphilis, of leprosy, of cholera, of diphtheria, and of tuberculosis, in fact, there is no branch of pathology which has not benefited by his labours and by his research, and for the most part that famous series of volumes, VIRCHOW'S "Archives," keeps the record. Like other great men, VIRCHOW made his mistakes, but as often as not it was his own hand that led to his own undoing His view that the cells of connective tissue were able to take part in the pathological new growth of epithelial cells was based on erroneous observations and his explanation of the deformities and symptoms in cases of cretinism is founded on a pathology which is peculiarly narrow, while his opinion that the pathology of chlorosis could be explained on anatomical defects in the circulatory system and blood forming organs is clearly at variance with ascertained facts

RUDOLPH VIRCHOW is destined for ever to be remembered as the father of rational pathology and the first initiator of a philosophic system of medicine. Although his conception of disease has in no way elucidated the secrets of life or of protoplastic activities it has nailed the interpretation of the grosser phenomena of disease to the mast of cellular physiology

◆

The Present Position of Chemical Physiology

IN the lucid and suggestive Presidential Address delivered by Professor W D HALLIBURTON, F R S, before the Physiological Section of the British Association at Belfast, and published on p 787 of this issue of THE LANCET, he points out the important part which chemical and physico chemical investigation has played in physiological and pathological research within recent years and the increasing practical application of the results obtained. He deprecates the tendency of some observers to revive the vitalistic explanation (or so called explanation) of imperfectly understood physiological phenomena and suggests that our knowledge of physical laws cannot be regarded as final and complete—that the apparent failure of these laws to explain some phenomena in living tissues may be due to imperfect knowledge of those laws rather than to the operation of some "vital" force

Professor HALLIBURTON pleads for bold experiment and "bold theorising from experimental data" to stimulate and to suggest further ideas for investigation and further generalisations of scientific and practical interest, and herein lie a danger and a difficulty The danger is in the tendency, unconscious, no doubt, of some theorists to invest the theory with the importance of the experimental facts, the difficulty lies in the peculiar relation of the subject of chemical physiology (or rather of bio chemistry, to adopt the more comprehensive term recently introduced) to the medical practitioner's curriculum, for while a knowledge of certain elementary properties and reactions of the more important substances occurring normally or abnormally in the body or in its excreta is absolutely essential for the rational diagnosis and treatment of disease, and a practical study of such now finds a place in the course of work of every medical student, the majority of the substances are of such complexity, and the problems involved so abstruse, that the knowledge of chemistry and physics necessary for their comprehension is likely to be almost limited to the expert—chemist or physiologist. At the same time, the results obtained are of such fundamental importance and the generalisations deduced of such practical value that while theoretical considerations and the technical details involved in the investigations may well be left to the expert, a knowledge of the generalisations and applications is necessary to the practitioner This practical aspect of the subject is well brought out in Professor HALLIBURTON'S address, for example, he gives a brief review of the work of PAWLOW and the St Petersburg school on the chemical processes of digestion and a very interesting summary of recent work on certain reactions of the blood—namely, its bactericidal, globulicidal, antitoxic, agglutinating, and precipitating properties. PAWLOW has demonstrated that the process of digestion is a continuous one in which the various actions are adjusted to the needs of the organism—e.g the acid gastric juice stimulates the proper discharge of pancreatic juice and the chemical constitution of the juices may vary with the composition of the food to be digested this in addition, or as a corollary, to his well known work on the composition and secretory mechanism of the digestive juices

Another result of recent chemical research has been to bring into harmony various conflicting observations and as in the notable instance of internal secretions to demonstrate the inter dependence of the various organs of the body in respect of their functional activities and further to add to medicine some exceedingly valuable therapeutic compounds. To return to the blood reactions dealt with in the address they are largely the result of a combination of chemical and microscopical methods in research, a branch of the science of comparatively recent development but of widespread utility and the well known staining reactions of the blood corpuscles and other cellular elements of the body afford another example of this depending as they do upon differences in chemical composition brought out by micro-chemical methods. The five reactions obtained with the blood referred to by Professor HALLIBURTON in his address are all of practical importance that of the bactericidal and antitoxic properties in their relation to immunity active or passive is well known and the existence of alexines or *bacteriolysins* and *antitoxins* respectively has been demonstrated and their mode of action to some extent elucidated, since each seems to consist of two substances—an 'immune body and a 'complement." The agglutinative reactions of the blood with various bacteria are now matters of every-day routine in the diagnosis of certain bacterial infections notably typhoid fever The more recently discovered precipitation reaction in blood in which for the first time we have a delicate test for distinguishing between human blood and that of other mammals is probably destined to be of great medico-legal importance, since it is extremely sensitive and is obtained with dried blood or even with human blood mixed with that of other animals. This precipitating substance or *precipitin* is produced in the plasma of any animal by repeated injections of human blood, and is specific for human blood, though a slight reaction is obtained with that of monkeys. Similar *precipitins* can be prepared for the blood of other animals. The globulicidal property of the blood or its power of destroying red corpuscles injected from another animal, though of less direct practical value, has its importance in relation to transfusion of blood. The facts that none of these substances has yet been prepared in a pure state that their known chemical properties are few and that their mutual relations are practically unknown do not constitute a bar to the practical utilisation of the reactions which they produce, but only afford an indication of the necessity for further research

The present position of chemical physiology is in short, in the front rank of the collateral medical sciences and it is not too much to hope, in the words of Professor HALLIBURTON, that in the future not only physiology but also pathology pharmacology and even therapeutics, will receive new accessions to knowledge the importance of which will be enormous.'

Low Temperature Studies

THOSE who have carefully read Professor DEWAR'S Presidential Address to the British Association for the Advancement of Science, the substance of which we published last week, must acknowledge that he has been engaged in a fascinating though very difficult, field of research. The results so far gained however show that after all even when pursued with the utmost patience and skill, the ultimate aim is probably beyond human realisation. Again we have to recognise that finality is beyond our grasp All along the lines of scientific research there seems to be clearly indicated a limitation of human attainment, all that has been unfolded coming in the middle of a quite short scale, so to speak. We are able to discover and to discern only that which lies between narrow limits, all beyond being merely indications, mere shadows of a something which does exist. In regard to extremely low temperatures we are bound to acknowledge, at any rate, in accordance with Lord KELVIN'S clever deductions and experiments the existence of a definite zero of temperature as a fundamental scientific fact. And yet, with all the wonderful perseverance and skill with which as is well known Professor DEWAR has attacked the problem he admits that all efforts to attain a temperature lower than 13° absolute have met with failure and he goes even further and expresses the opinion that it is extremely improbable that the absolute zero will ever be reached by man. This is a somewhat disappointing conclusion in view of the extraordinary number of highly interesting facts which Professor DEWAR in his admirable researches has been able to add to our knowledge of the subject.

It is not too much to say that for all practical purposes. the real history of the subject commenced with Professor DEWAR'S determination to attack the problem Speculations as to the position of the zero had been considerable, as he shows, from the time of BACON to the present, but definite experimental work beyond the use of salt and snow the agents employed by BOYLE and others had not been made until in 1759 Professor BRAUN of Moscow succeeded in solidifying mercury by the use of a mixture of snow and nitric acid. The result was of course looked upon as a wonderful achievement, seeing how strongly rooted was the idea that fluidity was the essential quality of mercury Gradually the conclusion gained ground that whether a given substance was gas, liquid, or solid was a matter of temperature. The so-called permanent gases had however so far not been made to resign their normal physical state and BOYLE in studying the action of cold upon air made the quaint and remarkable observation that cold does not weaken the spring by anything near so considerable as one would expect" AMONTONS in 1702 and LAMBERT in 1779 by ingenious arguments based on the contraction of air under the withdrawal of heat, concluded that it may be inferred that the gaseous condition is caused by heat. What was the limit, then, under which gases would fall to be or in other words, what was the zero of temperature? Theory has given the answer, but practice has not yet enabled us to realise it because of the enormous difficulty—nay, impossibility, according to Professor DEWAR'S dictum—of preparing and preserving frigorific agents The problem, however, is not so much how to produce intensity of cold as how (to use Professor DEWAR'S words) to save it when produced from being *immediately* levelled up by the relatively heated surroundings By adopting vessels having a double wall, the annular space between being very highly exhausted, Professor DEWAR has been able to keep liquefied gases under much greater control Further, the high degree of vacuum necessary for the purpose may be obtained by filling this space with an easily condensable vapour and freezing it out Thus liquid hydrogen collected in such vessels with the annular space full of air immediately solidifies the air and thereby provides itself with a high vacuum. Machines are now made capable of producing liquid air for industrial purposes and liquid air has thus become a cheap commercial commodity Its use has already been advocated in our columns to supersede ether or other volatile liquids as a frigorific agent in surgery According to recent announcements, it is highly probable that the production of liquid air and hydrogen will be effected most economically by the use of machines producing cold by the expenditure of mechanical work.

Though absolute zero never has been reached and, as Professor DEWAR says, probably never will be reached, yet the successful production of excessively low temperatures has yielded results which are of the greatest importance. The cold so far produced has been sufficiently intense to involve the solidification of all known gaseous substances with the exception of helion. Low temperature *research, again*, has deduced that under the influence of intense cold the great majority of, and probably all (if the temperature be sufficiently low), chemical interactions are entirely suspended. And yet, paradoxical as it undoubtedly is, many varieties of micro-organisms *can* be exposed to the temperature of liquid air for a period of six months without any appreciable loss of vitality Seeds, also, steeped for hours in liquid hydrogen—that is, at a temperature within 20° of absolute zero, show a similar persistence of life—their vitality is unaffected, as is shown by the fact that after their immersion in this intensely cold fluid they germinate when sown as actively as seeds that have not undergone such treatment. It is clear that the conception of vitality based upon the maintenance of chemical activity must give way In such a case we appear to be face to face with a third state, as Professor DEWAR says, a new and hitherto unobtained condition of living matter, for at such a low temperature the ordinary chemical processes must cease. Another remarkable biological application of the results of low temperature research has been the freezing of bacteria cells into hard breakable masses from which it has been possible to express the cell plasma. Thus the typhoid organism has been submitted to the process with the result that the cell plasma has been obtained for the purpose of determining its toxic or antitoxic properties. This line of research is calculated to throw fresh light on the nature and treatment of disease Though, therefore, the absolute zero may never be attained, yet the exploration having that object primarily in view has yielded results of the highest value, inasmuch as, amongst other things, it has given us further insight into the nature of vitality and possibly a fresh means of determining the physiology of the specific disease producing organisms

The broad physical question, however,—What is the chemistry of extreme heat and extreme cold?—remains unanswered. It is but another example of our range of observation being limited to within the appreciable, the "ultra" is still beyond and probably will for ever, humanly speaking, remain beyond And it is so with the whole cosmos What is the range of space? What is matter? What are the number and kind of vibrations which set the waves of ether in motion? The human view of these things must necessarily be very narrow But this fact should not deter the work of unravelling some, at any rate, of nature's secrets so far as it is humanly possible to do so Even within these narrow limits there is an infinity of truths to bring to light. If the goal is not reached the reward is great, as Professor DEWAR'S researches on the attainment of low temperature abundantly show, and we may surely take heart that thus far we may (and should) go albeit no further The pendulum inevitably swings back.

Annotations.

"Ne quid nimis"

FUNERAL OF PROFESSOR VIRCHOW

IN our issue of Sept. 13th we briefly alluded to the funeral of Professor Virchow, which took place on Sept. 9th, and we now supply some additional details On Sept. 8th the body lay in state in the great hall of the Rathhaus, which had been draped in black for the occasion and everywhere displayed mourning emblems, the banners of the city and of the university being placed on either side of the catafalque and students with drawn rapiers forming a guard. At the funeral the Government was represented by the Minister of Education accompanied by the entire staff of his department, the Minister of Finance, the Minister of the Interior, and the Imperial Secretary of State for Foreign Affairs The Imperial Chancellor also sent a representative. The members of the Royal Academy of Science and of the university were present "*in corpore*" and delegates from the great majority of the German universities were among the company, together with many officers of the Army Medical Corps, in which Professor Virchow had served at the outset of his medical career The municipal council attended on behalf of the city and the presence of deputations from political and other societies testified to the active part which the deceased had taken in the public life of his country and to the reality of his political influence Large as the assemblage was, the number fell short of what it would have been but for the circumstances that the university vacations had already commenced, that Parliament was not in session, and that many public bodies were having their annual adjournment, moreover, the shortness of the interval between Professor Virchow's death and his funeral prevented not a few of his friends from paying him the last tribute of respect. The spacious town hall was, however, overcrowded, so that many of those who were invited had to remain outside, being unable to gain admission. The ceremony commenced with singing by the cathedral choir after which the Rev Mr Kirms preached a sermon. Professor Waldeyer then delivered an address in the name of the university the Academy of Science and other scientific institutions. Addresses were also delivered by Herr Träger on behalf of the political party with which the deceased had been connected and by the chief burgomaster on behalf of the city The funeral procession then started on its way headed by numerous associations political and other with their banners while the representatives of the Government and of the learned societies and corporations walked behind the coffin, together with the members of the municipality The procession which was over a mile in length, in its progress through the streets on the way to the cemetery of St. Matthew was everywhere received with signs of public sympathy and tokens of the esteem in which the deceased was held by his fellow-citizens

FISH AS FOOD

THE fact that fish is an important article *of diet is one* which will be universally admitted, but it is not generally realised that the British people make so little use of the opportunities which nature has provided for them in the rich supplies which are to be found off the coast. Some statistical tables[1] which are published by the Board of Trade give a good deal of information, and although in their present form they are of little interest to those who have not a general idea of the way in which the fishing industry is carried on, they very clearly show that a large quantity of the fish caught is sent abroad, instead of being used in this country and those who buy fish will be struck at the great difference in the price which is paid to those who catch it and the price which has to be paid to the fishmonger The total value of the fish caught and landed in the United Kingdom during the year 1901 was over £9 000 000 Haddock and herrings produced £2,237,196 and £2,028,781 respectively A little over a halfpenny a pound only was received for herrings (0 62d.) and three halfpence a pound was received for haddocks. Whether considered from the point of view of quantity or of money value these two fishes are the most important of those caught off our coasts. It is to be feared nevertheless that a small proportion only of the poor of the country have been able to obtain either of these in an appetising form at a low price. It is usually said that the poor are not fond of and will not eat, fish. This is a very old idea. It was stated in a series of articles written on the fishing industry more than 50 years ago It is said to-day It is perfectly true that the poor of London are not partial to fish which they have to cook for themselves. If any unprejudiced observer possessing a keen sense of smell will walk down the streets in which fish is exposed for sale on barrows he will not be surprised that this is the case. It is by no means true that the poor who live in fishing towns and villages object to fish It forms the most important part of the nitrogenous food which they take. The partiality for fish extends also amongst the people as far inland as the supply of fresh caught fish is obtainable at a moderate price. There are, of course, many parts of the country which by the nature of things cannot be so cheaply or so well supplied as the places near to the sea. For this reason it is a matter of national importance that the curing and preserving of fish should be well carried out. In this matter there is room for much improvement. To those acquainted with the common haddock of London it is only necessary to recall its iridescent appearance and ammoniacal odour Many of these fishes are in a state of partial decomposition when they are cured and the methods adopted are neither wholesome nor cleanly The local sanitary authorities are often disinclined to interfere with the arrangements of fish-curers sometimes perhaps, because they look upon their industry as the mainstay of the place, sometimes, doubtless because things have been so carried on time out of mind and what was good enough for their fathers ought, as they say to be good enough for them, for they are a conservative people. THE LANCET has had occasion to call attention to cases in which obvious sanitary rules were disregarded in the process of curing We wish that the authorities in fishing centres would realise that it is to their true interest as well as their duty to carry out the law in regard to nuisances If the fish-curers were more careful to ensure a good and uniform quality in their output they would enormously increase their trade and their profit. It is because fish preserved in this country is of such uncertain quality that the fashion of relying so much on foreign produce has become so very general and that sardines are so highly esteemed. *It is said that the English sprat tinned* in this country is now transported to France that it may be duly labeled and consigned to England for the benefit of those who eat sardines and practise ' economy at the same time. Good bloaters and kippers are superior in all respects to the cheaper sorts of sardines,' but at the present time they are not readily obtainable although nearly 2,000 000 barrels of herrings were exported last year chiefly to Germany

THE USE OF CHLOROFORM IN PARTURITION

WE publish in our correspondence columns a thoughtful letter from Dr T W Parkinson dealing with the use of chloroform in labour It is probable that Dr Parkinson has exaggerated somewhat in saying that the use of chloroform is at the present time much restricted in obstetric practice but none the less we commend his judicious remarks to the notice of junior practitioners. All medical students, in London at all events, now have to receive instruction in the use of anæsthetics, including chloroform, and we doubt not that among the cases which they have to conduct there would be no difficulty in including those attended in the maternity departments of the hospitals The objections to the use of chloroform have been of two kinds (1) the sentimental now happily set to rest by the more healthy tone of religious feeling and (2) the practical Dr Parkinson discusses these and we are in harmony with his contentions. It cannot be too *strongly insisted upon* that the administration of chloroform in labour differs in many particulars from that required for surgical operations hence the importance which Dr Parkinson rightly attaches to the need of giving students an opportunity of learning the special requirements of a woman in normal labour The gravamen against chloroform is we are sure not its use but its injudicious and ignorant employment. In most stages of labour chloroform should be given as an analgesic, not as a means of inducing full narcosis and the degree of narcosis required is the lesson to be learnt by the practitioner before he can obtain satisfactory results. The commission appointed by the Royal Medical and Chirurgical Society which presented its report in 1864 dealt with the assumed increased danger of post partum hæmorrhage and of peril to the child and its finding was that no such danger arose. This, we believe, is also the experience of all who have used chloroform largely in maternity hospitals. With regard to the supposed failure of tonus of the uterus and abdominal muscles in cases in which chloroform is employed the following points are worthy of notice. The influence of chloroform upon muscular tissue is not, according to most experimental results, very marked and is certainly far more delayed in the case of the musculature of viscera and the internal organs than in that of the skeletal muscles. Further, it is a well-known fact among surgeons that the abdominal muscles are among the last "to give" under chloroform In abdominal sections a most profound narcosis is required before complete relaxation of these muscles can be obtained—a far more profound narcosis than is ever needed for women in childbirth When these facts are borne in mind it is hard to understand why any experienced accoucheur should hesitate to spare the patient the pangs of labour It is quite probable that the casual way in which chloroform is given in many cases of parturition by nurses or persons quite uninstructed, or even by the patient herself, has caused the dread of ill consequences Chloroform so given may cause ill effects, and fatalities even have arisen, but it is quite unfair to attach the blame of such accidents to the use of chloroform.

ECTROMELUS

THE interesting case of ectromelus reported by Dr John McGibbon, which appears on page 811 of this issue, is not so very uncommon. Dr Gould and Dr Pyle in their "Anomalies and Curiosities of Medicine" give a number of instances, together with some curious illustrations A celebrated case of ectromelus, and one not mentioned by Dr Gould and Dr Pyle, was that of Matthew Buchinger He was a native of Nürnberg in Germany and was born on June 2nd, 1674 His upper extremities, to judge by his portrait, were somewhat longer than those of the child whose portrait we reproduce He is said to have been very accomplished, being able to play various musical instruments, including the flute. He could also write and draw coats of arms which were executed in Indian ink with a pen. He could moreover juggle and shave himself He was married four times and had 11 children and his total height was 29 inches He died in 1722. Possibly, however, the most remarkable example of this condition was the late Arthur Kavanagh, M P, a review of whose biography appeared in THE LANCET of March 14th, 1891, p 608 He suffered an intra uterine amputation of both legs and arms just below their upper third, and when little more than a boy he could write, draw, ride and drive, shoot, and fish He became a very fair amateur draughtsman and wrote legibly As to the use of this condition in fiction it will be sufficient to remind our readers of the recently published novel, "Sir Richard Calmady"

THE PROSTITUTION OF THE POST-OFFICE

WE received this week from a correspondent to whom it was sent a pamphlet describing and illustrating the use of a certain remedy prepared by a chemical manufacturing company in the United States of America. It has coloured illustrations of a young woman, more or less dressed in a frilled nightdress, with the remedy being applied to various portions of her body Our correspondent wants to know if it is decent that such illustrations should be dropped into the waste-paper basket of an ordinary household. He considers that some steps should be taken to lessen the burden of actual work entailed upon medical men in England by having to tear up the various advertising pamphlets which they get from St. Louis and elsewhere in the United States before casting them into a waste paper basket. We have upon many previous occasions referred to abominable advertisements issued on a post-card which can be read by anybody and everybody and containing flaming details about disorders of menstruation and other sexual complaints, and we cordially sympathise with our correspondent. It is perfectly disgraceful that the post-office should make itself the medium for the dissemination of abominations such as we have referred to and for the still more disgusting effusions sent out by the *soi disant* Dr Bell, the Reverend David Jones, the Reverend John Wilson, and other swindlers and quacks A new Postmaster-General has recently been appointed and we earnestly beg of him to introduce some method of stopping the dissemination of filth. It is useless to say that the post-office officials have not time! They have plenty of time to inspect envelopes containing invitation cards and to surcharge them as being in the nature of a letter, and if they can do this they can certainly stop "Dr" Bell and the other blackguards whom we have mentioned We are glad to see that our contemporary *Truth* refers to the matter in the current issue, but both *Truth* and ourselves have been trying for so long to get either the police or the post-office to interfere in the matter that we begin to despair of any remedy

THE DISTRIBUTION OF PLAGUE

A TELEGRAM from the Governor of Mauritius received at the Colonial Office on Sept. 12th states that for the week ending Sept. 11th there were 3 cases of plague with one death As regards Egypt the weekly return issued by the Director General of the Sanitary Department states that from August 25th to the 31st there was but 1 new case which occurred at Alexandria The number of deaths was 3 and 3 cases remained under treatment. With regard to sanitary measures there were 10,474 rooms disinfected and 398 limewashed. 247 sacks of effects were disinfected and 2137 sacks of rubbish were burned The number of rats killed and burned was 242 As regards Hong Kong, a telegram from the Governor, received at the Colonial Office on Sept. 16th, states that for the week ending Sept. 13th there was 1 case of bubonic plague.

THE AGAPEMONITES

THE recent occurrences at the headquarters of the almost forgotten sect of the Agapemonites lead us to remark that in nothing is the definition of insanity—viz., that it is a condition out of harmony with the environment—more justified than in the victims of religious enthusiasm and fanaticism. On the face of it Mr Pigott, who claims to be the Messiah, is either fraudulently deceiving his followers or else he is suffering from a delusion or from that form of religious exaltation which cannot be distinguished from it Now it is a peculiar fact that all historical accounts are clear about the admixture of the sexual element with ecstatic religious exaggerations, and the very name and the past revelations concerning the "Agapemonites" harmonise with the perverted cant, the spurious religious demonstration, and the sexuality which are so familiar to those conversant with the epileptic wards of asylums. In the desire for publicity, in their personal disregard of criticism and even of injury or violence at the hands of those who dissent from them, these fanatical upholders of morbid Christianity carry on their incoherent ravings with the same fervour as the Anabaptist dupes of John of Leyden and the befooled believers of Joanna Southcote It is very probably true that the action of some of the newspapers and of a section of the public in making these persons notorious is just what they desire and that the best way of treating them is to ignore them severely, but there is still a danger to society in the toleration of these enthusiasts, for of all people they are just those who recruit their ranks from the large number of hysterical and neurotic folk who are only too ready to fasten on to any cult of the moment which excites their impulsive organisations In Germany such a pretender would share the fate of the Faith Healers" and be promptly suppressed but the forcible extinction of any sect, however absurd, would in this country lead to indignant protest and to a rapid increase in the number of adherents to the persecuted cause, so easily is the insanity of sanity brought into evidence. In the present instance as in the past, we can but indicate the medical man as being the only means by which Mr Pigott and his co-delusionists can be properly dealt with A thorough medical examination by experts in the investigation of mental obliquity would probably result in the transference of impostors of this class to the seclusion of an asylum where their vagaries could only be carried on under restricted conditions. To deal with them as seriously deserving of logical treatment is as impossible as is the attempt to argue a general paralytic out of his fool s paradise

MASSAGE AND ' MASSAGE

IN that much perused romance of the last publishing season 'Kim" its author Mr Rudyard Kipling gives an elaborate description of the cure of the said Kim when suffering from general malaise, induced it would appear by prolonged fatigue, mental and bodily The Sahiba, in whose hands he was a half-comatose and wholly unresisting patient, began the treatment with what seem to have been very drastic emetics— drenches that smelt pestilently and tasted worse. She stood over Kim till they went down and inquired exhaustively after they had come up. Then, when the body was cleared she called in a sister practitioner— a cousin s widow skilled in what Europeans, who know nothing about it, call massage. Thereupon, the two of them, laying him east and west that the mysterious earth currents which thrill the clay of our bodies, might help and not hinder took him to pieces all one long afternoon—bone by bone, muscle by muscle ligament by ligament, nerve by nerve. Kneaded to irresponsible pulp half hypnotised by the perpetual flick and readjustment of the uneasy chudders that veiled their eyes, Kim slid 10 000 miles into slumber—36 hours of it—sleep that soaked like rain after drought. On emerging from this, the Sahiba fed him on fowls, vegetables, spices, milk, and onion, with little fish from the brook—anon, limes for sherbets, quails of the pit, then chicken livers upon a skewer with sliced ginger between. As the result of this massage (which Europeans know nothing about), followed by the strangely-compounded meal (of which they are equally ignorant) Kim,' we are assured, sat up and smiled. The terrible weakness had dropped from him like an old shoe." He had it is right to say youth on his side"—such an allowance of it, in fact, as enabled him to survive first the massage" and then the meal." What, indeed but youth and a general resisting power as abnormal as the treatment can explain the fact that, already semi-comatose with histolytic waste in the system, he could yet find room in his circulation and excretive energy in his kidneys for the accumulation of still further waste contributed by a kneading process, uninterrupted for a long afternoon, and practised by two sinewy hags who did not leave off till every tissue in his body was reduced to pulp?" Kim s services to British rule in India were, Mr Kipling tells us, of signal value The bequest of his body to the museum of the Calcutta Medical College, in the remote contingency of his death would be of no less value to pathological science. But, persiflage apart, Mr Kipling s claim for the superiority of Hindoo massage, as practised by the Sahiba, over the European massage, as performed by an expert under duly qualified medical advice, is but another instance of the loose talk in which even clever men indulge on subjects outside their competence. Massage, in fact, since its revival by Dr Mezger of Amsterdam in 1853, has come to be employed in medicine only in a well defined class of cases—employed moreover by persons specially qualified and certified and acting under the direction of the physician or surgeon in attendance. In the training of such persons the Swedish schools—notably Stockholm and Upsala—have, greatly to their honour taken a lead, granting a diploma to aspiring 'masseurs and masseuses only after thorough examination. So practised and medically controlled massage is an important adjunct to treatment, steadily if slowly living down professional disfavour and misgiving due to such disastrous products as the mas age kidney"[1] and other such lesions which we hope Hindoos as well as ' Europeans will ere long know nothing about."

PTOMAINE POISONING

CASES of ptomaine poisoning have occurred in several places in addition to those which were mentioned in THE LANCET of Sept. 13th, p 756 and in each instance the source can be traced to pork pies purchased from the same pork butcher at Derby Six persons were seized at Sheffield, of whom one has since died. Several people were also attacked at Uttoxeter, one case proving fatal A family of seven persons at Walthamstow were taken ill after having partaken of a pie sent from Derby and at Cheltenham a number of persons were reported ill from a similar cause. Dr Sheridan Delépine has presented his report to the Sanitary Committee of the Derby Corporation on the samples of pork pie entrusted to him. He had succeeded in isolating a bacillus belonging to the colon group which he considered had produced the symptoms observed. The full report has not yet been published, but we understand that Dr Delépine is of opinion that the meat or the jelly, or both, used in the pies became infected in the course of preparation, whilst the flour, lard and seasoning of the pies were not contaminated. He further shows that animals inoculated with the bacillus have died and the same variety of bacillus has been isolated from the blood of those animals. If these statements have been correctly reported, the present outbreak cannot accurately be termed one of 'ptomaine" poisoning The symptoms were caused apparently by the toxins eliminated by the colon bacillus, and their pathology would materially differ from previous outbreaks which have been due to alkaloids formed by decomposition of organic substances due to putrefactive organisms

EXTRANEOUS DEPOSITS IN URINE

STRANGE errors occasionally are made in determining the nature and source of urinary deposits. Quite recently we received a communication from a correspondent who stated that he had been attending a patient suffering from subacu e muscular rheumatism and who had been taking a teaspoonful of sulphur in milk every night. The urine was slightly turbid and deposited amorphous sulphur Our correspondent had eliminated the usual sources of accidental contamination such as cleanliness of the collecting vessel and purposeful addition and asked for information as to whether sulphur could be eliminated by the kidney in a solid form. In a subsequent letter however he stated that he had questioned his patient more closely and he found that she had been in the habit of using a dusting powder containing sulphur for local irritation. A similar ca e was also brought to our notice in which a specimen of urine was sent for examination under the supposition that it contained amyloid corpuscles," bodies which somewhat resemble starch granules in appearance owing to their concentric variations. They occur in the semen and hence the practitioner who sent the sample thought that they might occasionally find their way into the urine. In this case also, questioning the patient showed that the source of the deposit was a powder containing starch In another instance, in which a urine contained a sediment of "uncertain character," microscopic examination revealed the presence of the threads of leptothrix buccalis together with fragments of meat and vegetable fibres, thus plainly indicating that the deposit originally came from the mouth Patients occasionally add substances to the urine for purposes of deception, but the above cases show how important it is not only to make sure that the collecting and examining vessels are perfectly clean, but that in doubtful cases the patients themselves should be carefully questioned as to possible sources of error Other extraneous matters also lead to mistakes and we have seen a fragment of pine wood from the floor mistaken for an epithelial cast, moreover, particles of silk, cotton, or linen fibres frequently puzzle students who are not conversant with their nature

[1] THE LANCET Oct. 2nd 1897 p. 878.

SNAKE-BITE AND SNAKE-LORE

THE subject of snake bite may occasionally engage the individual practitioner in a moorland country side where, especially in the summer and autumn, cases are not unknown of infants dying from collapse after being bitten by vipers We have recently been informed that the "infallible remedy" used by "Brusher" Mills, the well known New Forest snake catcher, for the bite of the adder or viper is the fat of the creature itself melted, bottled, and applied a drop at a time to the wound The cure, he asserts, is an affair of two minutes Mills has, of course, had immense experience with snakes, having in his day killed or taken more than 4000 venomous and 27,000 harmless specimens He has, in fact, practically devastated his own field of operations round Lyndhurst. His belief in his remedy is shared by Wiltshire and Hampshire rustics and is doubtless universal in the country districts of England. The question is whether this treatment is merely a survival of the old savage homœopathy which ordains a hair of the dog that bit you as a cure for the bite, or whether it is a rude form of serum therapy Vipers are exceedingly quarrelsome from the moment they break the egg and unless immune against venom would long ago have ceased to exist as a distinct species Hence their fat may be a kind of antitoxin. Of course, all fatty and oily substances are useful against poisons, which they doubtless absorb and isolate. The old fashioned "London viper catchers," mentioned by White of Selborne and others always employed hot olive oil as a cure or treatment for snake bite, and this with ammonia continues to be recommended We read ot the oil cure in works on natural history but find no mention of the peasants' use of fat. How came it to be used in the first instance? Probably in accordance with the savage theory that fat, blood, sputum and so forth, contain the life principle or "soul" of men and animals and are therefore a cure for any lesion. Fat was anciently used to frighten away serpents from gardens and houses The "suet of deer strewed up and down where they [adders] come will cause them to depart," says Agrippa of Nettesheim, whose ideas, despite his scepticism, were often those of the tribal medicine man. Bacon fat, mixed with the brains of a weazel, is recommended by him to scare away rats and mice. Drugs and charms obtained from snakes are, of course, very ancient The witches in *Macbeth* make a baleful viper-broth, but the same mixture was also a medicine and cure for many diseases. The sloughs of snakes had also singular uses. The sixteenth century Jérôme Cardan is quoted in an old chap-book as saying, "If any do sprinkle his head with the powder of a skin that a snake doth cast off, gotten or gathered when the moon is in the full, being also in the first part of Aries the Ram, he shall see terrible and fearful dreams And if he shall have it under the sole of his foot he shall be acceptable before magistrates and princes"

SCOTTISH POOR-LAW MEDICAL OFFICERS

SOME little time ago Mr Galloway Weir, M.P, asked for a return of those Scottish Poor law medical officers who had been dismissed by their parish councils The report is now published and shows "the number of medical officers dismissed by parish councils in each crofting county during each of the seven years 1895–1901, name of the parish council, and the cases in which a cause of dismissal was assigned." We publish this return with pleasure It will serve to show intending applicants for Scottish Poor law appointments which parishes should be avoided It will be remembered that English and Irish Poor law medical officers have a right of appeal to their respective Local Government Boards but the Scottish Poor law medical officer has none

County and parish	Number of medical officers dismissed	Date	Whether cause for dismissal was assigned
Argyll—			
Kilfinichen	1	1897	No
Caithness—			
Halkirk	1	1896	No
Inverness—

GENERAL PARALYSIS AND ITS TREATMENT BY THE MIXED METHOD

M DEVAY of Lyon published in *Le Progrès Medical* of August 23rd a communication regarding the treatment of general paralysis of the insane by the "mixed intensive" method of mercury and the iodides, a method allied to the treatment with benzoate of mercury published by Professor Lemoine and to which reference was recently made in these columns[1] He has treated in all 90 cases and gives the results obtained in 21 cases, the latter consisting of patients the course of whose illness was watched for some length of time The results obtained by M Devay are summed up by him under the headings of amelioration, remission, and morbification of the symptoms of general paralysis, and on the whole the issues were favourable Although accepting the theory of the "parasyphilitic" nature of the disease he does not regard the prognosis as altogether hopeless but thinks that patients should be submitted to treatment as early as possible. The treatment consists of injection of calomel into the muscular tissues daily for a week the single dose being one centigramme (one sixth of a grain) per injection. Potassium iodide in doses of from 10 to 15 grammes (from 150 to 225 grains) is also given daily by the mouth. Treatment is continued until improvement begins to appear

[1] THE LANCET Sept. 6th 1902, p 690 annotation On the 'Intensive" Mercurial Treatment of General Paralysis and Tabes Dorsalis

THE PHENOMENA ATTENDING STATES OF CEREBRAL COMPRESSION

IN an important paper published in the September number of the *American Journal of the Medical Sciences* and dealing with the subject of cerebral compression and its attendant symptoms as observed both experimentally and clinically Dr Harvey Cushing of the Johns Hopkins University attempts to correlate the symptoms with the nature of the lesion and to explain the mode in which death may result in severe cases. The pressure exerted by a foreign body such as a neoplasm or a blood-clot is mainly local and is partly transmitted irregularly to distant parts of the encephalon. In cases of increase of cerebro-spinal fluid as in acute hydrocephalus, generalised meningitis, and hæmorrhage into the subdural spaces at the base of the brain, there is a general increase of intracranial pressure. By making a trephine hole in the skull and fitting it with a glass plate the condition of the cerebral convolutions as regards their blood vessels and capillaries can be easily observed under varying degrees of induced intracranial pressure. The pressure on the brain in these experiments is exerted by a bag of indiarubber filled with mercury and inserted into the subdural space through a second trephine hole near or remote, varying conditions of pressure being obtained by connecting the bag with a tube attached to a pressure-bottle of mercury which can be elevated or lowered by a pulley This method, first used by Francois Frank and later by Horsley and Spencer is one that allows of all degrees and gradations of pressure being used. On watching the convolutions through the glass "window" Dr Cushing noticed the following results. First, when the pressure was slight a distinct dilatation was produced in the pial veins of the exposed convolutions. Secondly as the pressure was increased the venous dilatation increased further and at this stage ophthalmoscopic examination showed dilated veins in the optic papilla (stauungspapilla). Thirdly when the compression was further increased so that it equalled the capillary blood pressure or slightly surpassed it the convolutions lost their rosy colour and became blanched while the veins remained dilated as before and filled with dark blood Such a condition of the cortical substance, says Dr Cushing may account for the apathy or stupor which is associated with marked increase of intracranial pressure such as may arise from a subdural hæmorrhage and for the associated "stauungspapilla" which von Graefe was the first to explain correctly On producing pressure by a pressure flask charged with warm normal saline solution and connected below with the subdural space the three grades of pressure appearances produced in the convolutions as before mentioned could be reproduced In both kinds of experiments, however stimulation of the circulatory and vaso-motor centre followed, and after a short interval, the carotid blood pressure rose, the capillaries were forced open by the incoming blood, and the circulation was restored in the convolutions. Dr Cushing points out that the reflex mechanism which thus operated *vid* the vaso-motor centre was a compensatory one which permitted the circulation to be restored in the brain after temporary arrest had been produced by increase of intracranial pressure. It was also noticed that whereas the cardiac centre in the medulla oblongata held out longest the respiratory centre soon succumbed and grew paralysed if there was any considerable increase of pressure. Hence in cases of death from such pressure as produced both experimentally and clinically, arrest of respiration preceded that of the heart, a fact previously noted by Horsley and Macewen. Indeed Dr Cushing records a case of a man who had sustained a severe cerebral injury with hæmorrhage and great pressure upon the medulla and in whom the respiration ceased entirely Artificial respiration was constantly maintained for 23 hours, *during the whole of which time the heart continued to beat feebly* but the respiration was never restored. Dr Cushing also points out from his experiments (mainly on dogs) and from clinical observations that the failure of the respiratory centre is marked by an early stage of slow and shallow breathing and by an intermediate stage of the Cheyne-Stokes type before it becomes totally arrested, these conditions being therefore valuable prognostic signs.

SKIMMED MILK AND MORTALITY AMONG CHILDREN IN FRANCE.

FOR some time it has been observed that mortality among infants and children resulting from unsuitable or insufficient nutrition is far more prevalent in the north than in the south of France. Dr Girard and Dr Bordas have published a map on infant mortality giving the proportion of deaths due to athrepsia and gastro-enteritis. Of every 100 deaths among children 69 are attributed to these causes at Troyes, 63 at Rennes, 49 at Boulogne-sur Mer 62 at Amiens 56 at Lille and only 36 at Paris. Then going south of the Loire the proportion falls at once to for instance 31 per cent. at Toulouse, 12 per cent. at Béziers, and 6 per cent. only at Clermont. What seems at first sight a strange paradox is the fact that it is precisely in those provinces where there are the richest pasture lands and the most abundant supply of excellent milk that the children die from starvation. The reason is, however very simple. These provinces have a large home and export trade in butter and all the milk is skimmed to make butter In the south where there is no such trade the children are able to obtain some milk that has not been skimmed hence the startling difference in the death rates. In the great towns also though there are many other causes tending to produce athrepsia, still the milk supply is more strictly controlled by the local authorities and is therefore of a better quality than that which is obtained in the butter producing countries. In Normandy and Brittany notably the authorities seem afraid to interfere with the great local industry by insisting that skimmed milk shall not be retailed to the public as pure milk. According to the law milk should be sold in bottles with labels stating whether the milk is pure, slightly skimmed, or very much skimmed. Of course, it is impossible in practice to enforce such distinctions and indeed, this rule has done much harm, for under the cover of a label skimmed and perhaps adulterated milk has been sold which certainly was not fit for consumption under any pretext whatsoever The stress of poverty creates a strong temptation to buy the cheaper skimmed milk and thus the children are starved. Skimmed milk and flour or bread are boiled together and sometimes a spoonful of coffee or even of alcohol is added to it and very young children or infants are fed on this The nutritive part of the milk is exported abroad as Normandy or Brittany butter It is the skimmed milk that aids in "the manufacture of angels" which is the most lucrative phase of the baby farmer's business The peasant proprietor also is so eager to make the utmost profit possible that he cannot resist removing the cream from his milk even though he has young calves and pigs to feed. But he is careful to add to his skimmed milk some maize potatoes, and other substitutes for the cream before he gives this milk to his cattle He is not always so careful in regard to the children. All these abominations cry aloud for a more strict supervision and widely read papers like the *Matin* are now taking up this grievance. Statistics abundantly prove the great excess of athrepsia in those parts of the country where it is the custom to skim all the milk. Measures must be taken so that, in spite of the butter trade, children and infants may be able to obtain milk that has not been deprived of its nutritive qualities

THE PROGNOSIS OF PLEURISY WITH SEROUS EFFUSION

IT is now generally admitted that most cases of pleurisy with serous effusion are of tuberculous origin. Hence the question arises, What is the ultimate prognosis of cases of serous pleurisy? In *American Medicine* of June 7th Dr Richard C Cabot has published an important paper on the subject He has investigated the sequels of 152 cases of serous pleurisy in which there was no evidence of tuberculosis in the lungs or other organs Cases of dry pleurisy and of empyema were excluded He draws the following conclusions 1. 80 per cent. of the patients whose history was followed for five years or more were in good health (In more than half of these the history was followed for 10 years or more) 2. 90 per cent. of the patients were in good health from two to five years after the attack—that is, the pleurisy was not immediately connected with any other affection. 3 15 per cent developed tuberculosis of lung or bone, but in only 3 per cent. did the tuberculosis manifest itself within two years of the pleurisy 4 The type of tuberculosis which occurred was usually mild and the course was slow In half of the 23 patients who developed obvious tuberculosis death did not occur until five years after the pleurisy 5 In two cases a very rapid form of tuberculosis developed many years after the pleurisy (nine years and 16 years respectively) 6 Only one-fourth of those persons who remained in perfect health five years or more after the pleurisy had a family or personal history of tuberculosis, while of those who became tuberculous two-thirds had such history Hence the importance of the history in the prognosis 7 Recurrence of the pleurisy after recovery occurred in 3 per cent. of the cases Re accumulation of the fluid immediately after tapping was rare Dr Cabot made no attempt to ascertain in what proportion of his whole group of cases the pleurisy was tuberculous. His figures show that whether pleurisy is tuberculous or not the prognosis is good provided there is no family history of tuberculosis, that when the pleurisy is tuberculous the tuberculosis is of a mild form from which recovery usually takes place, and that even when the lungs are attacked later the type of the disease usually is mild.

THE ROYAL VICTORIA HOSPITAL, NETLEY

ATTENTION having of late been directed to the shortcomings of the large and imposing looking hospital at Netley we are led to offer some remarks on the subject. The present site was selected and the designs for the hospital and Army Medical School were prepared at the time of the Crimean war and there can be but little doubt that the choice of the position was influenced by the fact that it was close to, and easily accessible from, Osborne. Her late Majesty always manifested a keen interest in her soldiers, especially in those of them who happened to be sick and wounded, as Her Majesty's frequent visits to Netley showed. The hospital must therefore be regarded as an old one and it was erected at a time of transition when the present acknowledged principles of sanitary construction were not established or even generally recognised as they now are. It consists of a large undivided hospital building designed on the corridor instead of on the pavilion principle It may suffice to state that while the glass corridors occupy the sea front the wards, which are, of course, the essential part of a hospital, are at the back and have a northern aspect and are consequently deprived of sunshine In addition to this and to the deterioration consequent upon age and occupation the building has numerous structural defects and inconveniences in other respects so that as a hospital it is much below the standard of modern sanitary requirements The desirability of having an army medical college in London is also no new idea, but, as may be readily understood, it was a very difficult one to get carried out Now that this has been, or is being, done, however, it becomes a question as to how the Netley Hospital and institution as a whole can be best dealt with and utilised. Pending the settlement of this matter it may be well supposed that the Government cannot, for financial and other reasons, take any step The projected scheme for a new military hospital about to be erected on an open and admirable site near Portsmouth was not undertaken, we believe, with any view to the relief of Netley, but in order to provide an efficient substitute for the old military hospital at Landport at present used for the accommodation of the sick of the Portsmouth garrison As regards London, the site at Millbank is a large and open one and well suited, we should imagine, for the erection of a military hospital or medical staff college, or for any other similar purpose.

THE Senator Dr Enrico Bottini, professor of operative surgery in the Paduan School, is making a good recovery from the paralytic seizure described in THE LANCET of last week. From Freiburg-Breisgau, whither he was removed, we learn that he is slowly but steadily regaining motor and sensory power in the affected side, while his speech has returned and his mind has lost none of its clearness Accompanied by two of his colleagues in the University, Professor De Tora and Professor Carli, he has made the journey successfully to his villa, "Il Riposo," at San Remo, on the Ligurian Riviera.

THE winter course of post-graduate clinical demonstrations given at the Westminster Hospital will be held at the hospital on Tuesdays, commencing Oct. 7th and finishing Dec 9th The fee for the course is one guinea, but holders of the conjoint post-graduate ticket are admitted free Practitioners desirous of joining the course are requested to communicate with either of the honorary secretaries, Dr J Purves Stewart, 7, Harley-street, W , or Mr William Turner, 53, Queen Anne street, W Particulars of the meetings week by week will be found in our Diary

THE annual dinner of the old and present students of the Faculty of Medicine of University College, London, will be held at the Hotel Cecil, Victoria Embankment, on Wednesday, Oct. 1st, at 6 30 for 7 P M Mr Rushton Parker, professor of surgery in University College, Liverpool, will occupy the chair

CENTENARIANS —Mrs Betsy Moore died at Bishop's Teignton, Devonshire, on Sept. 14th, at the age of 102. She was born near Salcombe on Nov 22nd, 1800, and had lived all her life in Devonshire She was married 80 years ago and had had nine children, the eldest of whom is 77 —Mrs. Kirby of Preston, who is 103 years of age, went for a drive through the town in a carriage on Sept. 4th for the purpose of seeing the decorations displayed in connexion with the Guild Merchant celebrations The greater portion of her life has been spent not in Preston but in Elswick.

IMPUDENT QUACKS AND THE NAME OF *THE LANCET*

SOME time since we received a courteous letter from Dr W Irving honorary secretary of the Canterbury Section of the New Zealand Branch of the British Medical Association, forwarding to us a copy of an advertisement which is being circulated in New Zealand and which is attached to each bottle of the "Lancet Influenza Cure.'" We append below a reproduction of a portion of the cardboard case containing the bottle (Fig 1) and also the circular sent to us by our correspondent (Fig 2). It will be noticed that, although figures of a lancet and of a stethoscope are printed above, the type and general appearance would lead readers to infer that the quack "remedy" in question had the sanction and recommendation of this journal, especially when taken in conjunction with the words, "introduced and prescribed by Sir William Broadbent, &c. &c. &c" who of course, has not in any way sanctioned the use of his name. We thereupon wrote to our representative in New Zealand, requesting him to put himself in communication with the firm whose name was stamped upon the circulars. This he accordingly did and received the following replies —

KEMPTHORNE PROSSER AND CO'S
N Z DRUG CO LTD.

Wellington, N.Z. July 30th, 1902.

DEAR SIR,—In further reference to your letter of the 14th inst. concerning a preparation called "Lancet" Influenza Cure, we have been informed by our Head Office in Dunedin that a preparation so called has *been put up by our Christchurch House.*

Our Head Office is now taking this matter up and we hope in a few days to be able to send you advice, which we trust will be perfectly satisfactory to yourself and also to your London friends.

In the meantime,

We beg to remain, dear Sir
Yours truly
Kempthorne, Prosser and Co s
New Zealand Drug Company Limited
(Signed) ROBERT B WOOD Manager

Wellington, N.Z., August 4th 1902.

DEAR SIR,—Confirming our communication of the 30th ulto. concerning your letter respecting a preparation called the "Lancet Influenza Cure," and our intimation that the line is put up by our Christchurch House, we beg to state that we are now in receipt from our Head Office of further advice in this connection Our Head Office desires us to point out that the term "Lancet" refers to the Instrument The term is registered and the registration is accompanied by a sketch of the instrument as a trade mark. We might

INFLUENZA

—A Contagious Catarrhal Affection of the Respiratory tract, attended with much prostration, occurring for the most part in wide-spread Epidemics.

The symptoms are too well known to need amplification of description

According to Drs. Squire, *Bristowe*, Gull, Clarke, and others, the duration of the complaint *varied* from three days to a fortnight.

Under the most recent and effective treatment and *regime* prescribed by Sir Wm. Broadbent, the disease is *aborted* in its initiatory stage and

Within Twenty four hours the Patient has regained his normal condition of health.

The Lancet Influenza Cure is infallible in its action and as stated three doses effect a complete cure.

It is, and can be, exhibited in cases of Quinsy Diphtheria, Malarial Fevers, all Zymotic and Enteric diseases with absolute impunity and effects a marvellous restoration to health in [illegible] short period of [illegible]

state that in the advertisement also appears a diagram of the instrument You will understand therefore that the term Lancet" has no connexion whatever with the London journal of which you are the representative in the colony and we trust that you will take the earliest opportunity of advising the proprietors to this effect

We are, dear sir, yours truly
Kempthorne Prosser and Co s
New Zealand Drug Company, Limited
(Signed) ROBERT E WOOD Manager

It will be noticed that Messrs Kempthorne, Prosser, and Co have, as we anticipated, shielded themselves under the sketch of the instrument which they have artfully inserted in the advertisement What sort of connexion there is to be assumed between a lancet as depicted in the illustration and the treatment of influenza is difficult to imagine—the stethoscope might perhaps be of service but is not alluded to in the title of the "Influenza Cure", indeed, its introduction would foil the real intention which we have no hesitation in saying is to pass off the quack "medicine" under a guarantee, as it were, of the title of this paper Messrs Kempthorne, Prosser, and Co have made a most unwarrantable use—or rather abuse—of the name of THE LANCET If any similar attempt were made in this country we should at once proceed to set in motion the power of the law, and we have no doubt whatever that we should promptly be enabled to stop such a scandalous use of our title, but it is obviously difficult for us to take timely and effective proceedings in the very distant colony of New Zealand. Of this, of course, the drug vendors are aware.

Sir William Broadbent has been so good as to send us a copy of his correspondence with Messrs Kempthorne, Prosser, and Co, which is as follows —

Dunedin 24th July, 1902.

KEMPTHORNE, PROSSER & CO'S
NEW ZEALAND DRUG COMPANY LIMITED,
Dunedin, Wellington Christchurch Auckland
Cable Address: Cremation.

Sir William H. Broadbent,
84 Brook street
Grosvenor square, London

SIR—We have the honour to acknowledge your letter of 27th May last, as under —

To Messrs Kempthorne, Prosser & Co

"SIRS—I call upon you to desist at once from using an advertisement of a so-called influenza cure in which my name appears The use of my name in connexion with this cure is a fraud upon the public and a gross insult to me

Yours truly
(Sgd) W H BROADBENT"

The same morning that we received your letter we also received another letter from Dr W Irving Canterbury section of the B M A (N Z Branch) dated July 17th in reference to the same matter We know nothing whatever of the circumstance here at the head office but at once wrote Dr Irving as duplicate letter herewith and also to our branches making inquiries in respect to this matter and we now very much regret to find that our Christchurch Branch had been selling the article referred to the Lancet Influenza Cure" bearing Sir W H Broadbent s name

We sincerely regret this circumstance and now fully apologise to you for having used your name without authority

We enclose you duplicate of correspondence with Dr W Irving in which you will see the matter fully explained and that we have given instructions to promptly stop the using of your name and to at once destroy any printed matter which we may have in possession bearing your name The manager of our branch who set this thing in motion is now out of our service and the only explanation the present manager can give is that he copied this prescription from The Lancet However that is a matter of no moment whether it was copied or whether it was not we had clearly no right in any way to use your name and we again apologise for this unwarrantable liberty

Sir we are yours truly
Kempthorne Prossor & Co s
New Zealand Drug Company Limited
THOMAS M KEMPTHORNE,
Managing Director

It will be noticed that "the manager of our branch who set this thing in motion is now out of our service, and the only explanation the present manager can give is *that he copied this prescription from The Lancet*" Nothing more is needed to show the real intention of the quacks whose action we consider to be fraudulent as well as dishonourable.

THE NEW SANATORIUM, WEYMOUTH—The new sanatorium at Weymouth, of which the Dowager Duchess of Beaufort laid the foundation stone in the early part of last year, is now completed The buildings, which will form one of the finest charitable institutions in the South of England, have been erected at a cost of about £20,000.

UNIVERSITY OF LONDON FACULTY OF MEDICINE

INTENDING students of medicine, or their parents on their behalf, will naturally seek for information as to the extent to which the reconstitution of the University of London has modified the conditions of education and examination in the Faculty of Medicine In the Students' Number of THE LANCET (August 30th, 1902, p 576) there are set out extracts from the official regulations relating to the degrees in medicine which are issued by the University The careful reader of these extracts, comparing them with those published in the Students' Number last year, will find practically no change, except as regards the matriculation examination, the revised regulations for which are fully set out below If he has also been a careful reader of the medical press during the long period of agitation that preceded the reconstitution of the University, the fact that so little change has been made will cause him some surprise if not disappointment. Further consideration will perhaps indicate that slow progress in effecting changes was from the nature of the case to be expected and will in the end prove advantageous. In an essentially conservative country like England it is inevitable, in order that sufficient energy should be generated to effect a reform, especially a reform in connexion with education, that the evils to be removed and the benefits to be anticipated should be loudly proclaimed by those promoting legislation It is also necessary for the promoters of legislation to take advantage of any added power that may be gained by associating in the movement reformers who do not entirely appreciate that the particular change they desire will not be directly brought about by the legislation proposed. A want of appreciation of these facts is leading to a good deal of discontent and to a certain amount of misdirected energy amongst medical teachers in the University A careful examination of the position of affairs will enable an estimate to be made of the prospect of carrying out in due course wise reforms in medical education now that a complete teaching university is established In the first place, it must be admitted that for all practical purposes, so far as the Faculty of Medicine was concerned, the unreformed University of London was a teaching university All candidates for degrees in medicine were required before presenting themselves for examinations subsequently to the preliminary scientific examination to produce certificates of instruction in recognised medical schools Such medical schools were in fact though not in name, constituent colleges of the University and by means of such of their teachers as happened to be members of the Senate or university examiners these schools exercised a considerable, though indirect, influence both upon the curriculum and the examinations It is undoubtedly due to these facts that the degrees in medicine alone, of all the degrees of the London University, were held in high esteem by the community at large as well as by graduates of other universities, and that the Faculty of Medicine, although without definite constitution, was the recognised chief power in the University Thus it came to pass that the teachers of medicine in London, though suffering less disabilities than the teachers of any other subject and having less to gain by the change, were nevertheless the chief actors in the long struggle which led to legislation two years ago To maintain the interest of the teachers in this wearisome contest against the strong party who resisted all reform it became necessary constantly to call attention to the grievances of the student of medicine who desired to obtain a degree in London Whatever was not perfect in medical education in the metropolitan schools was attributed to the faulty constitution of the University To strengthen the desire for reform imperfections were sought for and made much of, whilst their removal was confidently predicted by the reconstitution of the University, regardless of the fact that many of them were of collegiate and not of university origin The complaint that has been constantly made in the medical press for the last 15 years or more that the education in the schools was not coördinated with the examinations of the University, and that consequently students of average ability could not reasonably expect to obtain medical degrees in London, was undoubtedly necessary to provide the motive for reform. At the same time the publicity given to this statement has tended to lessen the entries of medical students in London and has thereby limited the finances of the schools and prevented them from maintaining their pre-eminence. Whether the reconstitution of the university will speedily effect the improvements in medical education that are anticipated depends upon the appreciation of the fact that so far as the Faculty of Medicine is concerned the step already taken is an exceedingly small one and in itself accomplishes very little. The schools of the University in all other faculties have by the reconstitution of the University been immediately placed in the position already occupied by the schools in the Faculty of Medicine. To the teachers in the schools of science, arts and literature it may be enough to rest from their labours and allow natural development to take its own course. For the teachers of medicine to rest content with what has been already effected would be the surest way for them to lose the pre-eminent position which has naturally belonged to the metropolitan medical schools in the past but which has in recent years been seriously challenged by some of the provincial schools.

In the following paragraphs an attempt has been made to forecast the future work of the Faculty of Medicine and to estimate the fitness of the powers with which it has been entrusted to carry out such work thoroughly and speedily

THE FACULTY OF MEDICINE ITS COMPOSITION AND POWERS.

As originally constituted by the statutory Commissioners the Faculty of Medicine was composed of 150 members, consisting of the senior professional staff of the hospitals and the chief lecturers in the medical schools. One of the first acts of the Faculty was to draw the attention of the Senate to the fact that the selection of recognised teachers to be members of the Faculty which had been made by the Commissioners left much to be desired, and to request the Senate to admit to the faculty (1) every person recognised as a teacher of one of the subjects of ‘ advanced medical studies” (2) every person recognised or provisionally recognised as a teacher of one of the subjects of intermediate medical studies” and (3) at least one recognised or provisionally recognised, teacher in each subject of preliminary medical studies from each school of the University in the Faculty of Medicine.

The Senate acceded to this request and as a result the Faculty as now constituted consists of about 350 recognised teachers of the various subjects of the medical curriculum. It is probably the largest body of medical teachers that has ever been officially constituted as a permanent committee to deal with questions of medical education. It contains men of world wide reputation in connexion with nearly every subject of the medical curriculum and comprises representatives not only of every medical school but of the chief special hospitals in London. In addition to the powers delegated to this large body of men under the statutes of the University it will undoubtedly possess great influence over the constituent medical schools, over the medical profession and when necessary over the general public. Upon the success of the Faculty in influencing the general public depends perhaps in greatest measure its power of improving medical education. Not only in London, but throughout the United Kingdom, the one most serious bar to the perfection of medical education is the complete indifference of the public to the fact that it is any concern of theirs. This indifference is due to a want of knowledge as to the needs of medical education It is a primary duty of the Faculty of Medicine to make these needs known Medical education, like every other form of higher education, requires endowment. It cannot be efficiently carried on without it. Endowment must be provided either by the State or by private munificence. On the continent of Europe endowment is provided by the State where the education of each medical student costs his country between £20 and £50 per annum. In America assistance to medical education has in recent years been provided by the princely benefactions of private donors To a certain very moderate extent the example of America has been followed by some of the provincial towns in the United Kingdom. In London medical education is entirely unendowed. The newly-constituted Faculty of Medicine of the University of London must see that its University is amply endowed and that a due proportion of its endowment is devoted to the furtherance of medical education. The public has become so accustomed to impose upon the medical profession the task of giving free service to the sick poor that it sees no injustice in demanding that the medical staff of the great hospitals shall also bear the burden of carrying on the education of medical students without endowment. It must be pointed out to the public that the burden is becoming intolerable, and there is no body of men to whom the public will be more disposed to give a sympathetic hearing than the physicians and surgeons who constitute the main portion of the Faculty

The association together for the purpose of promoting medical education of representative teachers from each of the medical schools of the University should have the most salutary effect upon the schools themselves. The almost internecine struggle between the metropolitan schools of medicine should now cease As constituent colleges of a great University the former rivalry of the schools must give place to concerted action in an endeavour to coördinate for the benefit of all students the unrivalled facilities for clinical investigation afforded by the greatest city of the world Already there are encouraging signs that the University will break down the barriers between opposing schools and help them to appreciate that the prosperity of all is bound up with the prosperity of each. Working hand in hand, supplying each other's deficiencies, some specially developing their teaching in one direction some in another and all granting facilities to each other's pupils these great hospitals in London may yet form a coherent centre of teaching worthy of their past records. With regard to this coördination and cohesion of the schools the Faculty of Medicine should exert great influence.

Another indirect effect that may be anticipated from the influence of the Faculty of Medicine is a diminution of the importance attached to examination in the scheme of education. It is perhaps an exaggeration to say as some have done, that we are within measurable distance of regarding examinations with the respect paid to them by the Chinese, but few will deny that examination holds too high a place in general estimation. In no class of education is this more so than in medicine. It is inevitable that examiners should be selected from those who have formerly distinguished themselves as teachers and that Senates and other supreme educational boards should consist chiefly of those who are actively engaged as examiners rather than as teachers. The Faculty of Medicine is the only body in the University interested in medical education which contains a majority of teachers as opposed to examiners and these teachers must make their power felt if the reconstituted University is to be a teaching university in fact as well as in name. Much of the above work the Faculty must achieve by indirect influence rather than by means of reports and recommendations officially presented to the Senate. In this more limited sphere there are, however many important problems awaiting solution or only partially solved, and they will be briefly alluded to under separate headings.

ADMISSION TO THE UNIVERSITY MATRICULATION

The inadequate endowment of higher education in the United Kingdom and the rapid multiplication of universities are likely in the near future to give rise to serious problems Inadequately endowed educational establishments can only manage to avoid bankruptcy by attracting large bodies of students large classes being obviously more economically taught than moderate-sized ones. So long as the bait used to attract students is the renown of the professors and the high reputation of the degrees of the university the competition for students has only a good influence upon education. For an inadequately endowed university the temptation may arise to endeavour to attract students by requiring a low standard of preliminary education from those seeking admission to its colleges and by granting its degrees on easy terms. Such methods of competition amongst universities cannot fail to have the most disastrous effect upon education. There is some reason to believe that their operation may be already noticed in the case of certain universities so far as their medical degrees are concerned. They are more likely to take effect in the Faculty of Medicine than in any other faculty because degrees in medicine have a definite commercial value inasmuch as they admit their holders to the Medical Register and confer certain rights of professional practice When so many important towns in the United Kingdom are clamouring for university charters it is well that this problem should be carefully considered The Government should be prepared adequately to endow every local university to which it grants a charter or at least should previously satisfy itself that adequate endowment is forthcoming from private munificence. Failing this desirable way of placing universities beyond the temptation to compete unwisely for students, medical education might be saved from the evil effects of such competition by the establishment of a single State examination for admission to the Register. Meanwhile, one of the first duties of the reconstituted University of London has been to determine the conditions under which it would admit undergraduates within its gates. On all hands it was agreed that there should be no lowering of the standard of preliminary education required of students seeking admission. It was decided that as in the past a matriculation examination conducted by the University itself should be imposed upon all candidates except those already possessing degrees in certain selected universities. The nature of this examination has, however, been the subject of prolonged controversy. The regulations for the examination as finally approved are printed below. In deciding upon the subjects and scope of the examination the Senate had the advantage of the assistance of a special advisory board containing such valued representatives of secondary education as the headmasters of several public schools, and the scheme finally adopted differs but little from that originally drafted by this body. It may therefore be confidently hoped that the new matriculation examination will be more acceptable to public schoolmasters than was its predecessor. The Faculty of Medicine, when asked by the Senate to report upon the question of the matriculation examination, laid stress upon the fact that the old style of examination was so out of line with the education in the ordinary schools that many boys of more than average ability were obliged to leave the best public schools and to be privately coached before submitting themselves for the test. The Faculty, therefore, reported "that no scheme of matriculation will be satisfactory which does not provide a wide choice of subjects for examination so as to meet the requirements of candidates whether from the classical or modern side of secondary schools." Such a wide choice is now provided, and although there is a fear expressed by some lest intending students of medicine should make an unwise choice there can be no doubt that a judicious widening of the gate of the University will have a good influence upon education. Single handed no university can alter the course of study pursued in our secondary schools, and the efforts of the old London University in this direction have had but the smallest effect upon preliminary education, while they have led to the exclusion from the University of many very desirable students whose school work had not been conducted upon the exact lines laid down by the Senate. The Faculty of Medicine may congratulate itself that it has taken an active part in removing what has for years been regarded as one of the chief obstacles to a reasonably accessible degree for London medical students. At the same time those who have regarded the old matriculation examination as the "goal of secondary education and the gate of the University" may derive some satisfaction from the knowledge that the Senate is taking active steps in coöperation with other universities to establish "school leaving" examinations. A well considered joint scheme of "school leaving" examinations conducted by several universities should be a very valuable means of coördinating and systematising secondary education throughout the country.

PRELIMINARY AND INTERMEDIATE MEDICAL STUDIES

"*The Senate shall use its best endeavours, whenever practicable, to secure common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres.*"

These are the words of one of the clauses of the new statutes of the University and it is no exaggeration to say that so far as medical education in London is concerned the Senate has no more important task to perform than the satisfactory solution of the problem thus entrusted to it. The statutory Commissioners frankly stated that they considered the need of concentration of preliminary and intermediate medical education to be clearly established and that they would have preferred to have themselves framed statutes for at once effecting it. To have done so would too long have delayed the publication of the statutes and they therefore "empowered and recommended the Senate to proceed as soon as may be in the desired direction." One of the first acts of the Faculty of Medicine was to elect three members to represent it on the Senate. The choice of these senators was in great measure determined by the wish of the Faculty that its representatives should be prepared to impress upon the Senate the desirability of carrying out the recommendation of the Commissioners with regard to concentration. Little time was lost in calling attention to the statute relating to this subject and in moving the senate to refer the matter to the Faculty of Medicine. The Faculty conferred with the medical schools and found, as the Commissioners had stated, that there was no consensus of opinion in regard to the mode in which concentration should be carried out. Nevertheless, a committee of the Faculty was able to draft a report containing a specific recommendation that the first step should be taken by establishing in the near neighbourhood of the University a school of anatomy, physiology, biology, and chemistry under conditions which so far commended themselves to the Faculty that the report was adopted without dissent for presentation to the Senate. This first stage in the proceedings was reached in December, 1901. Since that time the Senate and the Faculty have been in conference upon the provision to be made in the proposed school and it is probable that early next session an appeal will be made to the public for funds for its establishment. Should the response be sufficient to enable the University to carry out the wishes of the Faculty there will be established in London an institute of medical sciences second to none in the United Kingdom, and one to which the metropolitan hospitals will be able with confidence to entrust the preliminary training of their students. Such opposition as still exists to "concentration" depends on a fear lest in the two or three centres to be established the teaching of anatomy and physiology should be less well done than it is at present in the 12 competing schools. The report of the Faculty on the accommodation and staff of the proposed institute should do away with any fears of this kind and enable the teachers in the schools to feel that they cannot more certainly promote the welfare of their students than by helping the University to secure the funds to build and to endow the institute. For not only will the accommodation and facilities for study in the new institute surpass those at present provided in the medical schools, but, relieved of the necessity of teaching these earlier subjects, the schools will be enabled to develop the teaching of the clinical period.

ADVANCED MEDICAL STUDIES

"*The Senate may make arrangements with the Royal College of Physicians of London and the Royal College of Surgeons of England, or either of them, to conduct jointly with the Senate examinations in such portions of the subjects included in the course of study for a medical degree as may be agreed upon between the Senate and these Colleges, or either of them.*"

Last year we called attention to this permissive clause in the statutes and urged that advantage should be taken of it as soon as possible. It is satisfactory that the question is now under consideration by all three bodies concerned. If some feasible method of diminishing the number of examinations for the London student of medicine who desires to obtain both the university degree and the college diplomas can be arranged it will be of great assistance to the authorities of the schools. The constant interruption of systematic study caused by numerous examinations is a great stumbling block to education. During the five years' medical curriculum a student without once being referred may under existing conditions present himself for 14 separate examinations in order to obtain the conjoint diploma and the university degrees.

It is hardly necessary to indicate the improvements that will be made in the clinical period of study in the schools of the London University when they are freed from the burden of the earlier subjects of education and their students' course of learning is less interrupted by preparation for a multitude of examinations. The laboratories of physiology and chemistry will be devoted to experimental and clinical pathology, to bacteriology, and to pathological chemistry. By coöperation with the special hospitals, and possibly also with the workhouse infirmaries, the course of clinical instruction may be amplified and made more illustrative of the vast material available amongst the 5,000,000 inhabitants of the metropolis. With well equipped clinical laboratories and with wards filled with cases selected with due regard to educational needs there is no doubt that the high standard of teaching for which the London medical schools have been noted will be maintained and enhanced by their closer association with what is destined to become one of the greatest of modern universities.

The new regulations for the Matriculation Examination did not reach us in time to be inserted in our Students Number of August 30th They are now printed below

NEW REGULATIONS FOR THE MATRICULATION EXAMINATION

The following indicates the general scope of the new Matriculation Examination for all students. The first examination under the new regulations commenced on Sept. 15th. An examination under the old regulations will be held in January 1903, and under both sets of regulations in June, 1903. Candidates shall not be approved by the examiners unless they have shown a competent knowledge in each of the following subjects, according to the details specified under the several heads —1. English. One paper of three hours 2. Elementary mathematics. Two papers of three hours each 3 Latin, or elementary mechanics or elementary physics (heat, light, and sound) or elementary chemistry or elementary botany One paper of three hours in each subject. 4 Two of the following subjects neither of which has already been taken under (3) One paper of three hours in each subject If Latin be not taken, one of the other subjects selected must be another language from the list, either ancient or modern —

Latin.
Greek.
French
German.
*Arabic.
*Sanskrit
*Spanish.
*Portuguese.
*Italian.
*Hebrew
History Ancient or Modern.
Logic.
Physical and General Geography

Geometrical and Mechanical Drawing
Mathematics (more advanced)
Elementary Mechanics.
Elementary Chemistry
Elementary Physics —
(*a*) Heat, Light and Sound, or
(*b*) Electricity and Magnetism.
Elementary Biology —
(*a*) Botany or
*(*b*) Zoology

* Candidates for examination in these subjects must give at least two months' notice

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8233 births and 4683 deaths were registered during the week ending Sept. 13th. The annual rate of mortality in these towns, which had been 15 2 and 15 9 per 1000 in the two preceding weeks, further rose to 16 4 per 1000 last week. In London the death rate was 16 8 per 1000 while it averaged 16 2 in the 75 other large towns. The lowest death rates in these towns were 6 9 in King's Norton and in Halifax, 7 2 in Burton upon Trent, 7 6 in Hornsey, 8 5 in Handsworth, 8 9 in Leicester and 9 2 in Smethwick and in Blackburn the highest rates were 21 8 in Middlesbrough 22 5 in Preston, 23 0 in St. Helens, 23 9 in Liverpool and in Warrington 25 0 in Tynemouth, 25 5 in Portsmouth, and 26 6 in Merthyr Tydfil. The 4683 deaths in these towns last week included 1062 which were referred to the principal infectious diseases, against 638, 743, and 895 in the three preceding weeks of these 1062 deaths 704 resulted from diarrhoea, 107 from whooping-cough 85 from measles, 63 from diphtheria, 54 from fever (principally enteric) 45 from scarlet fever and four from small pox. No death from any of these diseases was registered last week in Burton upon Trent, King's Norton, Rochdale, or South Shields, while they caused the highest death rates in West Ham, Portsmouth Birkenhead, Wigan, St. Helens, Preston and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Newcastle-upon Tyne and Bristol from diphtheria in Portsmouth and Wigan from whooping-cough in Hanley from "fever" in Ipswich, and from diarrhoea in Bootle, Merthyr Tydfil, Willesden, Plymouth, Preston, Birkenhead, St. Helens, and Portsmouth. Scarlet fever did not show a marked excess in any of the towns. Two fatal cases of small pox were registered in London and two in West Ham but not one in any other of the 76 large towns. The number of small pox cases under treatment in the Metropolitan Asylums hospitals, which had been 128, 109 and 95 at the end of the three preceding weeks further declined to 71 at the end of last week seven new cases were admitted during the week, against 18 11, and 12 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2623, 2651 and 2713 on the three preceding Saturdays, declined again to 2669 on Saturday Sept. 13th, 311 new cases were admitted during the week, against 296, 295, and 333 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 136, 139 and 123 in the three preceding weeks rose again last week to 134 but were four below the corrected average number The causes of 46 or 1 0 per cent. of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Portsmouth Bristol Bolton, Salford, Bradford, Leeds, Sheffield, Newcastle-upon Tyne, Cardiff and in 47 other smaller towns the largest proportions of uncertified deaths were registered in Smethwick Blackburn Preston, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 14 4 14 0 and 13 9 per 1000 in the three preceding weeks, rose again to 14 8 per 1000 during the week ending Sept 13th and was 1 6 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 6 6 in Leith, 12 5 in Perth, and 12 9 in Greenock, to 14 5 in Edinburgh 16 1 in Glasgow and 16 7 in Paisley The 479 deaths in these towns included 21 which resulted from diarrhoea, eight from scarlet fever seven from measles and from whooping-cough, five from diphtheria, and four from fever In all, 52 deaths were referred to the principal infectious diseases last week, against 52, 45, and 54 in the three preceding weeks. These 52 deaths were equal to an annual rate of 1 6 per 1000 which was 2 1 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhoea, which had been 22, 14 and 31 in the three preceding weeks, declined to 21 last week, of which 11 occurred in Glasgow and four in Dundee. The deaths from whooping cough, which had been 17 and eight in the two preceding weeks, further declined to seven and included four in Glasgow The fatal cases of measles, which had been five, four and six in the three preceding weeks, rose to seven last week, of which three were registered in Edinburgh and two in Glasgow The deaths from fever which had been four and six in the two preceding weeks, declined again to four last week, and included three in Glasgow and one in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 68, 54 and 61 in the three preceding weeks, further rose last week to 82, and were slightly in excess of the number recorded in the corresponding period of last year. The causes of four or nearly 1 per cent. of the deaths registered in these eight towns were not certified.

HEALTH OF DUBLIN

The death rate in Dublin which had been 20 6 and 22 7 per 1000 in the two preceding weeks, again declined to 19 1 per 1000 during the week ending Sept. 13th. During the past four weeks the death rate has averaged 20 5 per 1000 the rates during the same period being 16 0 in London and 13 9 in Edinburgh The 139 deaths of persons belonging to Dublin registered during the week under notice included 38 which were referred to the principal infectious diseases, against 24 and 28 in the two preceding weeks, of these 19 resulted from diarrhoea, 6 from measles three from fever and two from diphtheria, but not one from small pox, scarlet fever or whooping cough. These 30 deaths were equal to an annual rate of 4 1 per 1000 the death-rates last week from the same diseases being 4 1 in London and 1 8 in Edinburgh. The fatal cases of measles, which had been 16 11, and 10 in the three preceding weeks, further declined last week to six. The deaths from diarrhoea, which had been three, seven, and 10 in the three preceding weeks, further rose to 19 last week. The mortality from both diphtheria and fever was the same as that recorded in the preceding week. The 139 deaths in Dublin included 48 of children under one year of age and

26 of persons aged upwards of 60 years, the deaths of infants considerably exceeded the number in the preceding week, while those of elderly persons showed a slight decrease. Six inquest cases and four deaths from violence were registered, and 42, or nearly one third, of the deaths occurred in public institutions The causes of seven, or 5 per cent, of the deaths registered in Dublin were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Fleet Surgeon E J Biden to the *President* for recruiting duties and medical department, temporary Surgeons P T Sutcliffe to Gibraltar Hospital, J S Dudding to the *Hibernia* for the *Maine*, G Taylor to the *Antelope*, G R MacMahon and Ramsey M Richards to the *Vivid*, Albert X. Lavertine to the *Lizard*, and Edwin S Miller to the *Impregnable*

ROYAL ARMY MEDICAL CORPS.

Major S C Philson proceeds to the South Eastern District for duty Captain F S Brereton will shortly embark for service in India. Major J H. E Austin embarks for Singapore for service in the Straits Settlements Lieutenant-Colonel J R. Dodd proceeds to the Woolwich District pending embarkation for service abroad Lieutenant-Colonel G Coutts is appointed Staff Officer to the Principal Medical Officer, Second Army Corps Lieutenant-Colonel D L Irvine embarks for service in India. Captain G S Mansfield is ordered to proceed to the Home District for duty with the Grenadier Guards, in succession to Major J H. E Austin. Major S Hickson is appointed to the medical charge of the Hospital for Soldiers' Wives and Children at Devonport and Lieutenant-Colonel R. J Fayle, D S O, is selected for duty in the Western District.

Lieutenant-Colonel William H. Allen retires on retired pay Dated Sept 17th, 1902

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Major G R. Gilruth having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers Dated Sept 17th, 1902.

Surgeon Captain F W Grant to be Surgeon Major Dated Sept 17th, 1902.

MENTIONED IN DESPATCHES

The *London Gazette* of Sept. 12th publishes a series of despatches relating to the Lango Expedition against the Soudanese mutineers in which the "greatest credit" is given to 'Dr Bagshawe for having, under the most adverse circumstances, successfully battled with the outbreak of small pox which unfortunately broke out and so greatly hampered the movements of the force" Major C Delmé-Radcliffe, the officer commanding the Lango Field Force, referring to Dr Bagshawe, says 'I cannot speak too highly of this gentleman or of the manner in which he performed the very hard work which fell to his share. He was never sick, whenever required he accompanied the troops any distance on foot, and he was wonderfully painstaking and successful in his treatment of his patients, black and white alike, and they numbered hundreds daily He acquired a well deserved measure of popularity with the whole force and I think the Uganda Protectorate is to be congratulated in retaining the services of so able and zealous a medical officer"

In a despatch relating to the Aro Field Force in Southern Nigeria the High Commissioner says —

> 'The medical staff was organised from the civilian staff of the Protectorate by the principal medical officer Dr Robert Allman and was augmented by a medical officer Dr Brook accompanying the Northern Nigerian Contingent and a medical officer Dr Hadley specially engaged to accompany the Lagos Column The organisation of the medical staff in the field was I understand found to be thoroughly efficient at all times and of that of the Base Hospitals I can speak personally having visited and inspected them on several occasions The organisation was I consider everything that could be desired in this direction and when the difficulties of transport especially of the wounded is considered it will be understood that there was great difficulty in rendering them of practical assistance Such hospitals were during the conduct of affairs established at different times at Itu Opobo Degama, Aro-Chuku, and Bende. I consider that Dr Allman is deserving of great credit for the successful [illegible]ner in which he organised his department
>
> I [illegible]ld bring the name of Dr A H Hanley senior medical officer of the Civil Medical Staff of this Protectorate, to your notice for [illegible]ble consideration on account of services rendered in the field when [illegible]nying columns. This officer volunteered to come out from England to assist in the operations, though his leave was but half completed His devotion to his work and care to the sick and wounded of whom he appeared to have had more than his share was remarked by every one connected with the force, and he is, I consider, the officer, as representing the medical department, whose services are deserving of special mention I should, however point out that all civilian doctors who volunteer to take part in the operations of this nature are deserving of great credit, for they have little or nothing to gain thereby and suffer in nearly all cases pecuniary loss in the matter of private practice"

Lieutenant-Colonel A Montanaro, who commanded the Aro Field Force, states that—

> "Dr R Allman, C M G, who was principal medical officer, not only made excellent arrangements before the expedition but supervised the carrying out of them to my entire satisfaction and it is mainly due to his forethought that abnormally good health prevailed among the Europeans and natives of the force
>
> Dr A H Hanley performed his duties as senior medical officer with great devotion I have never met a more attentive or conscientious medical officer"

The name of Surgeon Captain W Fletcher, D S O, Royal Army Medical Corps (Militia), is also mentioned.

HOME FROM THE WAR.

The large number of soldiers who have already arrived, and are still arriving, in this country from South Africa to be discharged the service form a difficult problem to deal with. Apart from those who from disablement from wounds or sickness are unable to earn a livelihood but are deserving of every consideration there are a still larger number of men who are seeking, but unable to find, employment It goes without saying that the Government and large firms and employers of labour are desirous of doing their best for these men, but it is nevertheless not by any means easy to find employment for them As regards those who are suffering from the results of sickness or disablement directly attributable to the war and field service, it is the obvious duty of everyone to help them as far as practicable With every desire in the world to treat the Boers with all possible generosity and friendliness as fellow subjects of the King it must nevertheless be acknowledged that there was a good deal of force and common sense in what the Marquis of Londonderry said in speaking at Stockton on Tees on behalf of the Soldiers' Help Society "He could not but think that the crowds which had during the past few weeks in the neighbourhood of London and in the South of England cheered the Boer Generals, who were mainly responsible for the prolongation of the war and its attendant misery and sorrow, would have been much better employed in seeking to give practical and material assistance to their own gallant countrymen who had fought and bled in South Africa."

WHAT THE SOUTH AFRICAN ARMY MEANT

We referred very briefly last week to the total losses sustained during the war in South Africa from wounds and injuries and from disease. It appears that the military forces in South Africa from 1899 to the end of July, 1900, that is to say from the beginning to the end of the war, according to the recently issued Parliamentary return, amounted altogether to 265,132 (officers and men) Of the reinforcements 337,219 were sent out from home, 18,534 from India, 30,328 from the colonies, and 52,414 raised in South Africa—making up a total of 438,495 This is more than eight times the number of a single army corps (52,000), which was considered at first to be sufficient. Apart from the lists of killed and wounded in numerous engagements published during the war, those of deaths from disease were first issued in December, 1899, and were regularly continued throughout the war The last recorded death in action was three days after the declaration of peace

NEW ROYAL ARMY MEDICAL CORPS WARRANT

An Army Order, dated Sept. 1st, just issued, contains a Royal Warrant relating to the medical officers of the Household troops It sets forth that commissions as surgeon lieutenants in the Household Cavalry shall be given, on the nomination of the titular colonels of the regiments, to persons approved by the Secretary of State Lieutenants and captains of the Royal Army Medical Corps attached to regiments of the Household Cavalry at the date of the warrant may, on the nomination of the titular colonels of the regiment, be transferred thereto in the rank of surgeon lieutenant and surgeon-captain respectively A major or lieutenant-colonel of the Royal Army Medical Corps may, on the nomination of the titular colonel of the regiment, be transferred from his corps into the rank of surgeon major or surgeon-lieutenant-colonel respectively in one of the regiments of Foot Guards.

OFFICERS MESSES.

A circular has been sent out by the War Office notifying that it has been decided to furnish at the public expense officers messes and the quarters of unmarried officers of field and lower ranks at the home stations Each officer on joining the service will be supplied with a field kit free of charge but to be kept up at his own expense The kit consists of a portable wood camp bedstead with canvas bag for the same three blankets, tripod washstand camp chair pillow valise for bedding canvas waterproof wash basin, bath, and bucket.

THE MEDICAL DEPARTMENT OF THE WAR OFFICE.

Our service contemporary the *Army and Navy Gazette*, understands that there is every chance of the Medical Department of the War Office, now at 18, Victoria street, being shortly removed to a more commodious building in the same street.

Looking Back.

FROM

THE LANCET, *SATURDAY*, *SEPT 18*, 1824

To the Editor of THE LANCET.

SIR,—The reason I address you on this subject may at first sight, not a little surprise you but there really is nothing known to the medical profession of hydrophobia, in fact, all our present means are totally inadequate to cure this direful malady Two cases within this last week, have occurred to my knowledge, one I had every opportunity of watching the other at Guy s, which you, no doubt, will notice. There did not appear in either of the above cases any very evident diminution of the disease from the treatment employed and so it has been for ages past and so will continue, unless something be done or something found out to overpower this great and determined enemy of the healing art But on account of the death of the first case (which became, almost directly known in every neighbouring part) a man who resides at Wing in Buckinghamshire, (at the request of some private individual in town who had heard of his notoriety entirely unconnected with the deceased) came to the friends of this poor mortal, and declared that, had he seen the man a few hours before his death, he would have cured him. This of course was thought almost too contemptible for notice however the man made his appearance and I of course, conversed with him on the point in question, and he declared that he would venture his life on any case, if he administered his medicine or saw it administered to the patient He gave me several cases to read one where two apothecaries after a variety of means, had come to the determination of bleeding the patient to death but someone who had seen the case and also knowing this man, had him directly sent for and the patient was placed under his treatment and recovered and is now living with many others in that neighbourhood, to attest the fact, where the man has also lived since his birth If this, hereafter should be found correct what neglect and blame will be attached to the names of these medical men. Think not that I am coming forward to espouse the cause of quackery for I assure you no one detests the traffic more than myself. But here stands the monster which defies all our power—the innumerable remedies we have proposed have all proved futile without exception therefore he who brings forward a cure is not only entitled to the highest encomiums of the medical profession but of the world and I do think it would be justifiable in any man s trying this remedy

I remain, Sir &c.

J H

Sept. 14th.

P S. The man s name is Thomas Newens.

Notwithstanding the conviction of our correspondent to the contrary we fear that the assertions of Mr THOMAS NEWENS are the boastings of an interested quack if they are not, how can he reconcile it to his conscience to quietly witness the destruction of so many of his fellow creatures when the publication of his remedy might rescue the sufferers from the agonizing tortures of the most terrible of all diseases

Correspondence.

"Audi alteram partem."

A PLEA FOR THE MORE FREQUENT USE OF CHLOROFORM IN LABOUR.

To the Editors of THE LANCET

SIRS —When Sir James Simpson first introduced chloroform into general use in Scotland and particularly in connexion with midwifery its administration was vigorously opposed by a large section of the public, and some of the old prejudice against its use still exists. This prejudice I am sorry to say is not entirely confined to laymen. I have heard medical men condemn in unmeasured terms the growing tendency to the free administration of chloroform in labour They maintain that it should not be given, except in cases of difficulty and they raise objections to it most of which appear to have their origin in a want of knowledge and practical training For 10 years I have used chloroform in all kinds of cases, having given it many hundreds of time and upon every possible occasion and I have never yet seen it give rise to any untoward symptoms. I go so far as to say that every accoucheur should educate his patients to its use, for in these matters as in most others progress can only be made according to the rate at which people are educated and prepared to receive its advantages. Everybody knows that a large majority of cases if left to nature will end satisfactorily as far as the safety of both mother and child is concerned. But by judiciously assisting the process the accoucheur can do more than this he can bring about the same happy result without permitting the mother to suffer all the agonising torture associated with parturition. It is undoubtedly the case that the conditions of modern life have influenced the process of parturition to an enormous extent. The mental as well as the physical torture in many cases is so extreme as to make it appear almost unnatural. Many instances have come under my own observation where the dread of a former parturition has caused much domestic unhappiness and has placed an absolute restriction upon reproduction. These are painful and difficult cases which most medical men meet with sooner or later and they should be overcome by assurances that the trials of labour can be alleviated in a great measure by rational treatment and management. The assurances can be carried into effect by the judicious use of chloroform. Not only will the pain be relieved but the mother's strength and energy will be conserved by preventing the unnecessary mental anxiety muscular straining and exhaustion To appreciate this one has only to note the contrast in the immediate after results between a case left to nature and a case in which chloroform has been judiciously administered In the former we find, as a rule, and almost always in highly nervous women careless exhaustion and indifference to her surroundings whilst in the latter you have a patient in good spirits, vigorous and keenly interested in everything In the latter also which is a matter of the greatest importance to those highly sensitive women the labour is robbed of almost all its painful after memories.

That anæsthetics are not more frequently employed in midwifery practice is not surprising when one considers the very imperfect practical training most men get in this important branch of their work in the various teaching centres If medical students were instructed how to use and to administer chloroform in a practical way and were at the same time urged to use it in midwifery cases upon every possible occasion, mothers would have less cause to dread their confinements. It is manifestly absurd that a student should never have the opportunity of giving chloroform to such cases as he may attend before qualification when immediately afterwards he may be called upon to do so in difficult cases where he cannot get help If chloroform is given with a knowledge of what is required—a knowledge which can be obtained by practical lessons only—there is not the least danger in its administration in confinements. I have not seen a case recorded where death was due to chloroform in such circumstances. It should be remembered that in addition to the intermittent administrations surgical anæsthesia is seldom required and that the maternal heart, owing to certain changes due to pregnancy is in a better and safer condition for the chloroform anæsthesia.

The most important argument against the use of chloroform in labour is the objection that it is said to interfere with normal uterine contractions There is no doubt whatever that if it is given, as is suggested by some, to the surgical extent as the head passes over the perineum it will interfere with normal contraction But this is the abuse of chloroform and not its use. If it is given on the open towel system, or any other system permitting a free admixture of air, and given intermittently and just before the onset of a pain, with few inhalations between the pains, the influence over the uterine contractions is very slight, if, indeed, there is any at all The little influence it may have is in my opinion beneficial. The onset of the contraction is not quite so sudden, but the frequency and force are maintained throughout. The relaxing influence exerted on the soft parts the freedom from struggling and unnecessarily contracting the muscles of the limbs and elsewhere, all help to render the uterine contractions more effectual and less painful. The abdominal muscles are very slightly influenced and continue to play their part as the uterus begins to contract If chloroform be given to the surgical extent and continued—a proceeding quite uncalled for in ordinary labour—the interval is lengthened, the force and duration are diminished, and, finally, the pains stop An important point, however, is the fact that even when deeply under its influence the uterus will contract as soon as it is emptied, but this contraction is not always a reliable one

Chloroform administration does not predispose to post-partum hæmorrhage unless it is given in complete ignorance of what is required and given with gross carelessness. If the absurd advice is followed of keeping back chloroform until the head is about to pass out and then give it to the surgical extent one is courting danger The exhaustion produced by this proceeding is greater than the exhaustion of leaving the case to nature to finish. In an ordinary case there is absolutely no necessity to give chloroform to the surgical extent at any time during the labour I have never yet seen a case of post-partum hæmorrhage associated in any way with the rational administration of chloroform. I would not hesitate to give it in a case with a predisposition to hæmorrhage, as I believe it would be beneficial if given judiciously from the fact of its conserving the strength and preventing nervous exhaustion, for the loss of the former and increase of the latter have, in my opinion, much to do with the production of post-partum hæmorrhage. The objection brought against chloroform that it is difficult to limit its action only holds good in very serious cases where prolonged surgical anæsthesia is required. Rest from pain, muscular straining, and mental anxiety can be obtained whilst the anæsthetic is entirely under the control of the administrator My advice to young practitioners in midwifery work is to give chloroform upon every possible occasion until they are thoroughly acquainted with its administration and to give it in the normal cases so as to be prepared for the abnormal. In cases of rigidity of the os, in the treatment of which the virtues of chloral have been so highly extolled, I would advise a trial of intermittent inhalations of chloroform preceded by a small hypodermic injection of sulphate of morphia.

In nervous women and those of highly developed intellect pain produces marked exhaustion and irregular muscular contractions which I believe seriously interferes with the normal uterine contractions in labour In these cases we find the most clearly demonstrated benefits of chloroform After a few inhalations the pains become much more regular and owing to the relaxation of the soft parts under its influence the labour proceeds much more satisfactorily Chloroform, or some mixture containing chloroform is the best anæsthetic in midwifery Ether is not practicable for single handed work and is much more objectionable to the patient when given intermittently

I am, Sirs, yours faithfully,

Sloane-street S W Sept 8th 1902.

THE LOW PHOSPHATES AND UREA IN THE URINE OF THE TUBERCULOUS

To the Editors of The Lancet

Sirs,—The perusal of Dr H. Harper's letter in The Lancet of Sept. 13th, p 776, on the deficiency of urea in the urine of tuberculous patients leads me to offer a few remarks on this subject. During a pretty long experience among tuberculous patients in Victoria Park Chest Hospital and elsewhere I have noticed how very rarely gout and phthisis are found together More than once I have come across tuberculous consumption coming upon a patient who years before had been subject to gout. Gout had quite left him and serious tuberculous disease had taken its place Free feeding and a fair allowance of alcohol is a method of treatment that certainly answers well in many consumptive cases Dr Walshe, in his lectures at University College, I remember, used to refer to cases of consumptive people who had gone in for rather free drinking and to the surprise of most who observed them found their lung symptoms to improve though there was no evidence of actual gout coming on Our good lecturer used to add for the benefit of his hearers "Do not let this statement lead any of you into dangerous ways" I have thought at times whether the administration of uric acid or urea to the consumptive with a view to producing gout might be a good therapeutic step, but I have never tried either of these bodies

Many years ago the late Dr Hastings of Albemarle street gave urate of ammonia, obtained from the pythons' house at the Zoological Gardens, for the cure of consumption and maintained his case so well before the Censors' Board at the College of Physicians that the late Dr T K Chambers was induced to try this curious remedy at St. Mary's Hospital under the name of "Mistura Pythonis," but the result of its administration was not encouraging, it seeming to have no action, either for bad or good, on the patients.

I am Sirs, yours faithfully,
John C Thorowgood, M D , F R C P Lond.,
Consulting Physician to Victoria Park Chest Hospital and to the Royal National Hospital for Consumption at Ventnor
Bognor Sept 13th 1902.

THE IMPUDENCE OF CERTAIN ADVERTISING DRUGGISTS

To the Editors of The Lancet

Sirs,—I enclose a copy of correspondence relating to "The Lancet Influenza Cure" with which my name was associated.[1] My attention has also been called to an advertisement of Kutnow's powder in the *Philadelphia Medical Bulletin* in which my name appears with a number of others around a portrait of the late Mr Lawson Tait as distinguished endorsements All the English physicians and surgeons pilloried with me are dead and their memory can be desecrated with impunity I enter a protest against this detestable practice in their name and my own.

To attribute to me any endorsement of Kutnow's powder is particularly unfortunate I have never ordered a single dose of it, but, on the contrary, have frequently had to point out that the habitual use of this and similar aperients is often most injurious and that the relief of constipation may be purchased very dearly The use of my name as recommending Kutnow's powder is, as in the case of "The Lancet Influenza Cure," a fraud upon the public and an insult to myself.—I beg to remain, your obedient servant,

W H. Broadbent, M D , F R.S
Brook street W Sept 16th 1902.

INSANITY AND LONG SEA VOYAGES

To the Editors of The Lancet

Sirs,—The excellent advice of Dr Louis Vintras on insanity and long sea voyages in The Lancet of Sept. 13th (p 775) deserves a very great deal of thoughtful attention on the part of the profession. More particularly does it concern the family physician who is often first consulted on the matter The curative effects of the ocean climate in certain diseases, such as, for instance, consumption, bronchitis, asthma, the after effects of inflammation of the lungs, pleurisy, &c , are familiar to all of us The various health voyages, the time of starting, the choosing a ship, the preliminary arrangements, the life at sea, the course, climate, and weather, and, not least, the management of the health at sea, are knotty points for him who seeks "the ocean as a health resort." Again, occupations and amusements, objects of interest at sea, future plans, and the end of the voyage all combine to make a sea trip pleasant or unpleasant. It is probable, too that the rapid improvement in the class of cases I have named is due to the following causes (1) enforced rest and change of scene (2) the constant *respiration of pure air free from* inert impurities and which is only to be found in sea air (3) open air treatment (4) greater equability of temperature and the soothing effect of ozone" on the constitution (5) certain specific substances in sea air (6) changes of climate through *the different regions of the ocean* These above conditions are what we realise in our mind when we contemplate sending to sea a patient of the class likely to derive benefit.

---

[1] See special article on "Impudent Quacks and the Title of The Lancet" on page 829 of our current issue —Ed L.

Nervous complaints are so numerous and varied in their *manifestations that they can only be spoken of generally* It may, however be stated broadly that for all those anomalous affections of the nervous system that are not accompanied by any actual disease of the brain or spinal cord but which are often dependent either upon mental causes or derangement of the digestive organs, we have in a sea voyage a most valuable and successful mode of treatment. In fact, there are no cases in which, as a rule the effects of sea life are more strikingly beneficial than in these. The change of scene, *the different mode of life, and* the varied social conditions, usually exercise the most cheering influence, not only upon the bodily health but also (which is equally important in complaints of this class) upon the mental state so that the nervous patient, after a month or two at sea, is often altogether a different being from what he was when he sailed.

But with regard to the more serious diseases of the nervous system such as paralysis epilepsy melancholia, and mania, it is necessary to speak much more guardedly, *and it is only after* all the *circumstances of such a case have been carefully weighed by the medical* man in attendance that it will be possible to form a decided opinion as to the advisability of a sea voyage. This extract from a sailor's log speaks for itself Having circumnavigated the ocean on more than one occasion I speak with some authority It is well to know the ropes and to be experienced before one gives an opinion Nevertheless, it is a good excuse to send a person of unsound mind to sea when you want to get rid of him. But the most honourable *action as a rule, is to advise the detention of a person* of unsound mind in a residential home where he will have a better chance of recovery —I am, Sirs, yours faithfully

Alton Hants Sept. 13th, 1902. J F BRISCOE.

A DISCLAIMER.

To the Editors of THE LANCET

SIRS,—The *British Medical Journal* published last week a short note by me on the use of paraffin for restoring the bridge of the nose. Some of the daily papers have made copy' of it, and have named me as though I had invented the method *I wish to say that I had nothing* whatever to do with the matter and I wish it could have been prevented.—I am, Sirs, yours faithfully

Sept. 15th STEPHEN PAGET

A MEDICAL ASPECT OF THE EDUCATION BILL

To the Editors of THE LANCET

SIRS,—In order that *education should be efficient* it is surely necessary that the children should be in the best possible condition for receiving it. It has long been known that the eyes of our board school children are defective and the recent discussion at the Otological Society clearly showed that the ears and throats urgently require attention. Apart from the special senses I would ask Does not the general condition of the children, especially as regards communicable diseases such as those of the skin and tuberculosis require supervision? If a child is compelled by law to attend school the parents have a right to demand that the child runs no risk by so doing The subject has been thoroughly recognised in some *countries—Germany* and Switzerland for example—where every child is medically examined on entering the schools and *all defects* are, as far as is possible, rectified. Such examination and treatment must be of the greatest value from the educational standpoint and must add to the physical and intellectual vigour of a nation. It seems clear that some system is necessary in this country

I am, Sirs, yours faithfully

Savile-row W Sept. 15th, 1902. ARTHUR H. CHEATLE.

THREADWORMS AND APPENDICITIS

To the Editors of THE LANCET

SIRS,—In an annotation in THE LANCET of Sept. 6th p 687 the occasional discovery of threadworms in the appendix is discussed It is there stated that Professor Bégouin could *find only a single reference to the existence* of threadworms in an excised appendix. It may therefore be worth noting that in a case of recurrent appendicitis occurring in a young woman I found at the operation that the appendix was *crammed with threadworms, in a lively* condition. The appendix itself was thickened but not ulcerated. Probably many similar cases have occurred without being recorded but in a large number of such operations I have only met with threadworms in this one case. Few things, however have really escaped the observation of our ancestors, and Santorini nearly 200 years ago (in 1724) in his careful description of the appendix noted that it was often the resort of intestinal worms and suggested that its function might be to *form a safe retreat for them to breed* in. This theory may not perhaps be generally accepted but no more ingenious one exists. It is of interest to note that the vermiform appendix was first described in 1524 by Carpi that Columbus was *interested in it, and that American* surgeons have since been prominent in demonstrating its importance. By a curious coincidence appendicitis was definitely described for the first time in 1824, exactly 300 years after the anatomical recognition.

I am Sirs, yours *faithfully*

J HUTCHINSON Jun

Cavendish-square W Sept. 15th 1902.

THE ELECTION OF A DIRECT REPRESENTATIVE TO THE GENERAL MEDICAL COUNCIL

To the Editors of THE LANCET

SIRS —The fact that Mr Joseph Smith has placed the medical profession of England and Wales to the great and totally unnecessary expense of a contested election for the office of Direct Representative raises a question which the personalities and professional positions of Mr Joseph Smith and Mr. George Brown would otherwise have rendered quite superfluous and *immaterial to the profession at large.*

The apology advanced by these gentlemen for Mr Smith's obtrusion on public *notice is that* he is supported in his action by the Medical Practitioners Association. Is this assertion correct?—in other words, have the members of that association been consulted on the matter and authorised this statement on their behalf? I am led to question this because there seems reason to believe *that the members of* this association are not even informed of matters which really are of direct personal interest and of the first importance *to themselves.*

If the members *of this* association are kept in ignorance of important facts it becomes all the more essential for a definite statement to be made as to the manner in which they have been consulted and have given Mr *Joseph Smith* their authority to represent their views at this particular juncture I am, Sirs yours faithfully

F ROS

Sept. 15th 1902.

THE PROPORTION OF THE MARRIAGE TO THE BIRTH-RATE IN DIFFERENT CLASSES OF THE POPULATION IN ENGLAND

To the Editors of THE LANCET

SIRS,—I quote an extract from the statistics of the County of London issued last week by *the London County* Council —

> There has been a decided improvement in recent years in the marriage *rate for* London. In 1894 it reached its lowest point—17 per 1000. In 1899 it was 18·4 per 1000. The birth-rate does not show a

corresponding increase *It is now at the lowest point it has ever touched* Thirty years ago it was 35 4 per 1000 in 1899 it had sunk to 29 3 In this matter the state of affairs in London corresponds in a surprising degree to the whole country where the fall has been on parallel lines The two poorest districts St Luke s and Bethnal Green, are proportionately the most prolific There are over four times as many births proportionately in St Luke s as in St George s Hanover square

With regard to these facts it would be interesting to know whether the experiences of other practitioners in other parts of the country are similar to mine. In the part of Devonshire where I have been in practice for many years it is quite the exception for any of the young married couples of the upper middle class to have any family at all Of notes that I have kept of marriages amongst private people of easy circumstances known to me, out of 47 marriages which have taken place between 1887 and 1900 31 have had no family at all—indeed, some of these have stated to their friends that they intend never having any—nine have either one or two children and the remaining seven couples have families of from three to five children. The same state of limited production prevails amongst tradespeople, though not to so marked an extent. As regards the labouring classes the birth rate appears to remain what it usually has been With regard to the scarcity of children amongst the educated classes I have a well grounded suspicion as to the cause As to the effect, if this state of things exists all over the kingdom it cannot but be serious

I am, Sirs, yours faithfully,

Sept 15th 1902 A GENERAL PRACTITIONER.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Increasing Plague Mortality —The Monsoon and the Famine —A Hospital Train for India —The Health Department in Calcutta

THE mortality from plague throughout India has increased during the past week from 3762 to 4371—chiefly due to the recrudescence developing in the Bombay Presidency The detailed figures are—Bombay Presidency, 3111 deaths, as against 2642 , Bombay City, 35, as against 22 , Karachi City, 11, as against five , Madras Presidency, 163, as against 145 , Calcutta City, 10, as against nine , Bengal Presidency, five, as against 10 , United Provinces, 195, as against 153 , Punjab, 63, as against 106 , Mysore 614 as against 612 , Hyderabad State, 143, as against 23 , and Berar, 21, as against 34 It will be noticed that the increase is for the most part general few areas showing any decline The disease is reported to be spreading in the Poona districts. The mortality is greater than at the corresponding week last year and that was higher than for the previous year It is therefore impossible to shut one's eyes to the fact that the outlook is very threatening and as so many more districts and provinces have become infected the recrudescence may probably culminate with a mortality larger than India has yet suffered A case of plague has been imported into Simla and has ended fatally 70 contacts were removed at once to the segregation camp Few people at home realise the enormous preparations which are being made for the great Delhi durbar and coronation festivities in January and the immense concourse of people which they will bring to that district. It is necessary to sound a note of warning that the anticipated plague outbreak may occur on or before this time and that if the infection spreads into the immediate vicinity of these places panic if nothing else may mar this great occcasion

Although the monsoon has to a certain extent been re established over Western India and rain has fallen in Gujerat and other famine areas it is as yet too soon to have had any effect upon the numbers under relief In fact, during the week ending August 22nd the number of persons under relief rose by 67 000 and the total is now over half a million, of which 371,899 are in British territory and 130,105 in native states.

The Government has decided to have special carriages to form a hospital train for annual use in conveying invalids from up-country stations to the sea and in time of war for carrying the sick and wounded from the base of operations to stations in India or to ports of embarkation. This train will be constructed on the principle of the Princess Christian hospital train used in the South African War The carriages will be the property of the military department, but will be maintained and kept in order by the railways concerned.

Several changes have been effected in the health department in Calcutta by the acting health officer, Dr T F Pearse They concern "an improvement in the registration of the cases of death by an inquiry upon the death of every person dying in Calcutta," the appointment of special food inspectors for each district, the appointment of an extra inspector of meat shops for the better inspection of these places and for the discovery of illicit slaughtering, the wholesale disinfection of tanks around which cholera has broken out, the compulsory registration of all burial grounds (of which I understand there are over 100), the issue of forms of notification for certain infectious diseases, the establishment of Hindu slaughter-houses in each district, and the reorganisation of the clerical work in all the district offices

August 30th

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Annual Inspection of the Corporation Hospitals

THE members of the Port Sanitary and Hospitals Committee of the City Council made their annual inspection of the various infectious hospitals on Sept. 9th The tour proved both interesting and instructive At Fazakerley a hospital of colossal proportions is now in course of erection. The large estate purchased by the corporation some years ago is already partly built upon, there being several wards for scarlet fever, typhoid fever, and other cases, now in use When the buildings are completed there will be provided two separate establishments, one of which will be specially set apart for the treatment of cases of small pox The visitors were generally struck with the scrupulous cleanliness, the brightness, and the perfection of the arrangements in all the hospitals At Fazakerley and Parkhill open spaces abound in which convalescent children can romp about The hospitals visited by the committee were those situated in Netherfield road, Fazakerley, Mill lane, Parkhill, and Grafton street. At the Mill lane hospital, the original accommodation in which had been increased by 88 beds in four wards, interesting ceremonies took place The Lord Mayor was invited formally to declare the new extension open and for that purpose was presented with a gold key subscribed for by the members of the committee Dr Thomas Clarke, the chairman of the hospital committee, was also presented with a similar gold key upon declaring the new pavilion open The past year has been one of marked progress for the city hospitals Seven years ago there were 400 beds under corporation control , there are now 950 beds. Last year 3337 cases of infectious disease were dealt with, and up to August 1st of this year 2900 cases had been treated. Less than a decade ago Liverpool was pointed to as a city hopelessly behind in the way of hospital accommodation for infectious diseases To day the city is better provided than any other town in England , and it is gratifying and reassuring to know that the city council, under the able guidance of Dr E W Hope, the medical officer of health, is acting in this matter with a liberality and enlightenment worthy of grateful recognition by the citizens of Liverpool.

The late Professor Virchow of Berlin

In view of the recent demise of Professor Virchow it may be interesting to recall the fact of his visit to Liverpool on Sept. 28th, 1898, on the occasion of the opening of the Thompson Yates Laboratories at University College by Lord Lister, an honour highly appreciated by the Liverpool school.

The Ninth Expedition of the Liverpool School of Tropical Medicine

Major Ronald Ross, C B , F R S , late I M S , the Walter Myers lecturer on Tropical Medicine, left London for Brindisi on Sept 12th, to inaugurate preventive measures at Ismailia on the Suez Canal against malaria Major Ross will take charge of the operations by special request of the Suez Canal authorities Sir William MacGregor, K C M G , the governor of Lagos, who has shown a lively interest in the operations of the Liverpool School of Tropical Medicine, and who has himself done such important work in the same direction at Lagos, has expressed a desire to witness Major Ross's operations at Ismailia and will join him at Brindisi They will proceed to Ismailia, where the Suez Canal Company has made arrangements to give them a suitable welcome.

Enlargement of the Liverpool Hospital for Consumption.

The recommendation of the estate committee of the City Council that the reversion of the premises, 70 Mount-pleasant, should be sold to the trustees of the Consumption Hospital for the sum of £400 subject to the consent of the Local Government Board and also subject to the condition that the existing premises shall be demolished and new hospital buildings erected within five years from the date of such consent, in accordance with plans and elevations to be approved by the corporation, was approved

Handsome Donation to the David Lewis Northern Hospital

Sir William Henry Tate Bart. has given the sum of £1000 to the David Lewis Northern Hospital for the purpose of endowing a bed to be named after his father the late Sir Henry Tate, Bart. This generous gift is a most welcome addition to the endowment fund of the hospital.

Infectious Hospital Accommodation at Prescot

The proposal to provide a new infectious hospital to accommodate children occupied the attention of the Prescot board of guardians at their last meeting The present buildings are altogether inadequate. The new hospital would cost about £5000 The matter was postponed for a fortnight in order that a complete scheme might be submitted.

The Maghull Home for Epileptics

Sir Alfred L. Jones K.C.M.G., has generously contributed the sum of £1000 towards the farm and extension fund of the home for epileptics at Maghull. This amount was promised last year conditionally on the committee raising a further sum of £9000 to enable them to purchase land for employing male patients and to carry out necessary extensions to meet the increasing demand for accommodation A few days ago the committee were able to intimate to Sir Alfred Jones that this condition had been fulfilled They also desire to acknowledge the liberality of the friends who have enabled them to achieve this happy result.

Opening of Morecambe Cottage Hospital

In beautiful weather the Morecambe Queen Victoria Cottage Hospital which has been erected at a cost of £3000 was opened on Sept. 9th by the Earl of Lathom. His lordship, as Provincial Grand Master of the Freemasons of the Province of West Lancashire was entertained at luncheon by the brethren of the Morecambe Lodge and the formal proceedings followed. Mr Thomas Baxter the chairman of the committee, presided, and later in the day handed over a full equipment for the operating theatre of the hospital. Lord Lathom opened the building with a suitably engraved gold key which was presented to him The institution was started free of debt a considerable sum however will be required annually to meet the working expenses of the charity

Sept. 16th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Sanitation in North Wales

THE Honourable Society of Cymmrodorion was founded under royal patronage in 1751 and it has for its object the bringing together of Welshmen especially those resident out of Wales with a view to advancing the welfare of their country Its especial aims are the improvement of education and the promotion of intellectual culture by the encouragement of literature science, and art, as connected with Wales Of late years there have been meetings of the society in Wales in connexion with the National Eisteddfod and at the Bangor meeting held on Sept. 8th a discussion took place upon National Health and Sanitation. Introductory papers were read by Dr Richard Jones medical officer of health of Festiniog and of the county of Merioneth by Mr D L Thomas, medical officer of health of the metropolitan borough of Stepney and by Dr Peter Fraser medical officer of health of the Carnarvonshire combined district Dr Jones urged the establishment of a public health department in connexion with the constituent colleges of the University of Wales at Aberystwith and Bangor upon the lines of that already organised at the Cardiff College. He advocated, also, the teaching of hygiene in the evening continuation schools and the founding of an eisteddfod health lectureship or exhibition from the surplus funds of the Eisteddfod Mr Thomas considered that sanitation was a national question and should be administered in all its aspects not from or by a small parochial body for districts that neglected to carry out their duties efficiently were a menace to the national health. Dr Fraser brought forward carefully compiled statistics comparing the birth rates and death rates of Wales and of North Wales with those of the whole of England and Wales and with other countries The period covered by these figures includes the last 30 years of the nineteenth century Although during these three decades there has been in the whole country a general fall in the birth rate, in South Wales the rate has always been above, and in North Wales it has always been below that of England and Wales. With regard to the deaths from all causes it appears that while there has been a considerable lowering of the death rate during the period named in England and Wales yet during the last decade of the century the death rate in South Wales was the same and in North Wales it was actually higher than that of the preceding 10 years. The number of deaths in North Wales from the so-called principal zymotic diseases compares favourably with that recorded in South Wales and in England and Wales, but with respect to the deaths from cancer tuberculosis and diseases of the circulatory system North Wales occupies a discouraging position. During the last 10 years of the century the cancer death rate in England and Wales was 760 per 1 000 000 of the population but in North Wales the rate was 1009 per 1,000 000 Both in North Wales and in the whole country the death-rate from all forms of tuberculosis has fallen during the past half century but in the 10 years 1891–1900 the North Wales death rate was 2244 per 1,000 000 while that of England and Wales was 2005 per 1 000 000 During the last 20 years of the century there was a considerable increase in the number of deaths from diseases of the circulatory system in North Wales, where during the last decade the death rate from this cause was 2145 per 1 000 000 compared with 1655 per 1 000 000 in England and Wales The principal cause of the high death rate from tuberculosis in North Wales in Dr Fraser's opinion is due to a great extent to the small badly ventilated damp, and often badly lighted bedrooms of many of the older cottages and the remedy obviously lies in building new and altering the old houses.

Women Sanitary Inspectors

The Newport corporation has decided, on the recommendation of the medical officer of health (Dr J Howard-Jones) to appoint a female sanitary inspector —The Worcestershire County Council are about to appoint a female health missioner for the urban district of Oldbury The county council will pay £50 and the district council £40 of the salary of the missioner

Bristol General Hospital.

The half yearly meeting of the governors of this institution was held on Sept. 8th, under the presidency of Mr Proctor Baker It was reported that the donations for the past six months amounted to £4233, including £1500 from Lady Smyth for the endowment of a bed in memory of her late husband. The chairman stated that the new out-patients department had been completed and was very satisfactory and the new post-mortem room was also finished. He added that the committee had undertaken to organise a hospital to meet the demands of Avonmouth in connexion with the new docks, Sir John Aird and Co. the contractors having agreed to defray all the expenses incurred.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Destruction of Diseased Meat in Dublin

A NEW refrigerator capable of making six tons of ice per day or producing an equivalent refrigerating effect, was formally opened by the Lord Mayor in connexion with the city abattoir on Sept. 15th. Town Councillor Clancy took the opportunity to call attention to the necessity of providing an apparatus within the abattoir for the destruction of offal and more especially of diseased meat. A deputation he stated from the corporation visited many continental cities some years ago and its report recommended the adoption of the Podewil system by which diseased meat and offal are converted into a dry powder which has a ready market as a fertiliser and as a food for swine, fowls, &c In Dublin as many as 108,112 pounds were destroyed in 1891, and 50,512 pounds in 1892 up to August 31st. This meat was in part surrendered and in part seized while coming into the city According to the present arrangement it is the custom to remove all condemned carcases from the abattoir through the public streets to the only place—a private establishment—where it can be destroyed Mr Clancy said that it was the duty of the civic authorities to erect such a form or destructor within the premises of the abattoir as would put the method of the disposal of diseased meat beyond doubt of question He stated that Sir Charles Cameron the superintendent medical officer of health, was in favour of some action being taken in the matter

Cork street Fever Hospital and House of Recovery

At the last meeting of the managing committee of the Cork street Fever Hospital the registrar reported that during the month of August the admissions were very numerous owing to the prevalence of scarlet fever, diphtheria, measles, and enteric fever Several cases of typhus fever were also admitted. All traces of small pox having disappeared from Dublin the convalescent home at Beneavin has been restored to its original use and is now filled with convalescents from scarlet fever, &c It will be remembered that in connexion with the last annual report of the board of superintendence of the Dublin hospitals it was notified that owing to the need of more suitable accommodation for the nursing staff the governors had purchased a site opposite the hospital gates on which they propose to build a house to accommodate 50 nurses The new building is to be called "the James Weir Home for Nurses in connexion with Cork street Hospital "

Sept 16th

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

Infant Mortality in New York City

DESPITE the low temperature in New York City this summer the increase in infant mortality has been marked The Board of Health has consequently been making a careful study of the recent vital statistics of the city The following figures show the deaths in Manhattan Borough in June of children under two years of age from diarrhœal diseases, with the humidity and temperature for each day On June 3rd the hottest day of the month, with a mean temperature of 78 6° F and 72 per cent of humidity, there were only three deaths in this class On June 29th, one of the coolest days, with a mean temperature of 60 6°, there were 12 deaths, and this day concluded a period of 12 consecutive days during which the mean average temperature was 65 5° On August 2nd, one of the hottest days of the month, there were 18 deaths in this class , while on the 3rd, one of the month's coolest days, there were 11 The two days of the heaviest infant mortality were relatively cool days with humidity of about the average These figures warrant no generalisation whatever

The American People Longer Lived than a Century Ago

The Census Bureau has recently published a report by which it is shown that the span of human life in the United States is steadily increasing The census statistics are taken by decades to compute the median age—that is such an age that half the population is under it and the other half over it. The median age of the inhabitants of the United States in 1900 was 22 8 as compared with 21 9 10 years previously The increase in the median age of the white population since 1810 is 7·4 years The Census Bureau chiefly attributes this gain in longevity to the remarkable progress effected in medical and sanitary science

Accident to the President

On Wednesday, Sept. 3rd, President Roosevelt met with an accident which but for his good fortune might have resulted seriously The carriage in which the President was driving from Pittsfield to Lenox was run down by a trolley-car near the Lenox Club All the occupants of the carriage were thrown out, and William Craig, the secret service man in attendance on the President, who was on the box with the driver, was hurled from the seat, run over by the car, and killed on the spot. The coachman was also thrown to the ground, sustaining a fracture of the skull from which he died soon afterwards The President himself escaped with a slight cut and bruise on the right cheek, his secretary, Mr George B Cortelyou, was severely cut about the face and the back of the head, while of the others in the carriage Governor W Murray Crane was slightly bruised. The accident is said to have been caused by the driver of the President's carriage attempting to cross the trolley lines diagonally, without noticing a trolley car which was coming up at a high rate of speed from behind The President's carriage was completely wrecked, and Surgeon Lung, who helped to care for the wounded, expressed his wonder that everyone in the carriage was not killed. At the time of the accident President Roosevelt was on a political tour of the New England States, and he decided to fulfil his programme which was nearly ended The news of the accident naturally produced consternation throughout the country, the more so, perhaps, as but such a short time has elapsed since the assassination of President McKinley

The Increase of Jews in New York

A decade ago there were 130,000 Jews in the whole of America, now there are 1,058,000—that is to say, nearly eight times more Jews are now in the country than there were 10 years ago The increase, however, in New York city has been most surprising A writer in a recent number of the *Jewish World* makes an elaborate estimate of the number of Jews in New York City based upon the statistics of Jewish marriages and deaths—principally the latter—during the past year, and he comes to the conclusion that the number of Jews in New York City is now close upon 600,000 These figures are probably not quite accurate, as they are founded upon the assumption that the Jewish death-rate is but five sixths as great as that of the total population of the city , nevertheless there can be little doubt that the Jewish inhabitants of greater New York are at least 500,000, nearly all of whom are in the borough of Manhattan—in fact, in New York City proper nearly one person in four is a Jew

The So called "Spotted Fever" of the Rocky Mountains

According to the United States Public Health Reports, August 15th, Surgeon J O Cobb of the United States Public Health and Marine Hospital Service, who was directed on June 23rd to proceed to Missoula, Montana, in order to investigate an outbreak of the so called "spotted fever" prevailing in that district, has recently handed in his report. This report is too lengthy to transcribe in full, but the following are the salient points For 17 years the disease has been known among the local practitioners of the Bitter Root Valley , it has always been limited to the spring months, no case having been reported later than July 20th and none earlier than one case of uncertain date in January Usually the first cases appear in March. All clinical experience goes to show that the disease is not contagious or infectious It is, however, without doubt an inoculable disease, as an intra corpuscular parasite has been found to be constantly present in the blood of each patient examined this year The organism resembles very closely Theobald Smith's Texas cattle fever organism, and it is certainly reasonable to believe, from the knowledge at hand, that this disease is introduced into man in the same way and in like manner as in the Texas cattle fever organism—viz., by the tick. The investigations undertaken go to show that the disease is confined to the Bitter Root and Lolo valleys, covering an area of about 20 miles in width and 40 in length Having found the intra corpuscular organism the next step was to find the host. After some trouble it was discovered that the host was not the tick, but some animal infested by ticks Finally the conclusion was reached that the animal in question was the "gopher," or ground squirrel, which is numerous in that very region in which the disease prevails Clinically the disease is curious Persons affected have a bluish spotting of the skin, the conjunctivæ are markedly infected, the tongue is moist but slightly coated, and the face and extremities are puffy and bloated but the skin does not pit on pressure The disease is extremely deadly , so far all cases this year have died, while only two bad cases with well marked eruptive lesions have been known to recover

Stokes and The Theory and Practice of Infant Feeding by Dr Chaplin.—The following are amongst the new works and new editions announced by Mr H. K. Lewis —Cancer of the Uterus a Clinical Monograph on its Diagnosis and Treatment, by A. H. N Lewers.—Handbook of the Pathology of the Skin, being an introduction to the Histology Pathology and Bacteriology of the Skin with special reference to Technique, by J M. H. MacLeod Assistant in the Bacteriological Department, Charing Cross Hospital.—A new (third) edition of Diseases of the Skin their Description Pathology, Diagnosis, and Treatment, by H. Radcliffe-Crocker the second edition of Hygiene and Public Health, by L. C. Parkes and H R. Kenwood and a new edition of Ophthalmic Practice, by Charles Higgens, revised with the assistance of A. W Ormond, ophthalmic clinical assistant, Guy's Hospital.

PRESTON AND COUNTY OF LANCASTER QUEEN VICTORIA ROYAL INFIRMARY —During the whole of the first week of September the city of Preston in Lancashire was given up to elaborate pageants ceremonial observances, social festivities and other manifestations of public rejoicing the occasion being the celebration of Preston Guild Merchant." Of all the Guilds Merchant that were held in mediæval times—and there were over 100 in England—that of Preston is the only one which now receives public recognition In early times the object of the organisation of the Gilda Mercatoria or Guild Merchant was the maintenance of the franchises and other privileges of the freemen, privileges which made it almost impossible for others than citizens to engage in trade. The first Guild Merchant of which there is any record was held in 1328. From 1542 down to the present date the Guilds have been regularly held every 20 years In 1662 the Guild and its concomitant festivities lasted for six weeks. On the *present occasion* the first event of the Guild was the procession with which the Guild Mayor (the Earl of Derby) went from the Guild Hall to attend Divine service in the parish church on Sunday August 31st, the sermon being preached by the Bishop of Truro. On Sept 1st a Guild Court was held in the Guild Hall, after which the the Guild Mayor again made a state visit to the parish church and then returned to the Guild Hall where lengthy Latin orations were delivered by the head master of the grammar school the head boy of the grammar school and the Recorder One of the events of Sept 2nd was a visit of the Earl and Countess of Derby to the Preston and County of Lancaster Queen Victoria Royal Infirmary where the countess opened the Diamond Jubilee Wing (Nurses Home) and the Robert Charles Brown operating theatre. The proceedings commenced with the offering of prayer by the Bishop of Burnley after which Mr W P Park chairman of the board of management, said that it was through Lord Derby that the Royal assent was given to the alteration of the name of the hospital, the motive of which was the fact that the building about to be declared open had been erected in commemoration of the late Queen s Diamond Jubilee. The architect then handed to the countess a gold key with which she performed the opening ceremony The company then proceeded from the Diamond Jubilee Wing to the operating theatre, the door of which the countess unlocked. At this point Dr Robert Charles Brown of Preston gave a short description of the operating theatre and Lord Derby then thanked him on behalf of the community for providing it, *constructed* and furnished as it was in every way according to the requirements of modern science. Dr Brown, in reply said that he had been connected for nearly 50 years with the infirmary and its predecessor the old Preston Dispensary There was no object more worthy of assistance than a hospital or *infirmary and it was* in this belief that he had made his various contributions to the Preston Infirmary A properly constructed and suitably furnished operating theatre was essential for surgical work As regards the organ he had personally experienced the delights of listening to a chamber organ during an illness and he had resolved that whenever *the opportunity* presented itself he would place one in the Preston Infirmary for the benefit of patients and officials alike The party then went to another portion of the premises where Lord Derby laid the foundation stone of the out-patients' department which occupied a detached position as it was thought desirable for several reasons to exclude the out-patients from the main building of the hospital. After the ceremony Dr Robert Trimble moved, and *Dr G C* Kingsbury seconded a vote of thanks to Lord Derby who made a brief reply and the proceedings then terminated

Notes, Short Comments, and Answers to Correspondents

THE SYSTEM OF PARISH NURSING

To the Editors of The Lancet

Sirs —I should be glad if any of your readers could favour me with any suggestion how to act in the following circumstances It so happens that a parish nurse is working in my district under the auspices of the vicar of the immediate locality and she in my opinion altogether exceeds the duties appertaining to nursing insomuch that she receives parishioners at her own residence tenders advice and treats what she fancies as simple cases at their *homes and that more or less frequently* without the intervention of a medical man regarding it as rendering first aid As an example, I may refer to a case recently attended by myself an infant about seven months of age was suffering from what I may be allowed to call malnutrition, and it appeared at least to the parents to be progressing somewhat favourably under the treatment which I thought fit to adopt After an interval of two or three weeks I was summoned to attend the child who was said to be suffering from convulsions which I could not recognise but I was surprised to find it had dwindled to a mere thread I commenced to reproach the mother as to the long interval (about three weeks) she had allowed to elapse without my seeing it; thereupon it was explained that it had in the meantime been taken to the parish nurse who advised accordingly *but that no medicine had been given.* The child died half an hour after my arrival I thereupon wrote to the nurse pointing out that what she really called first aid was in reality the last and that I should not feel justified in granting a death certificate without the coroner's sanction and moreover advised her to the effect that although she stood within her legal rights in practising medicine provided she did not pretend to be qualified which she does *not*, yet she must take the responsibility of the treatment on future occasions upon her own shoulders as I should be unable to give certificates in such circumstances I moreover advised her that the General Medical Council had prohibited qualified medical men from engaging the services of unregistered persons and that she could not reasonably expect medical men in the neighbourhood to become allied with her on the score that she was employed by an independent association when we are debarred from employing her in a like capacity as individuals. To avoid if possible, an inquest I next wrote to the coroner stating the case and as I said that I felt certain the cause of death was natural I asked as I was not prepared to state with any degree of certainty whether the infant would have recovered in the hands of qualified attendance if I might certify and received his assent I have refused to admit this nurse under any pretext to any house I attend for the reasons as heretofore

I am Sirs, yours faithfully

Sept 16th 1902. A Perplexed General Practitioner.

BLOOD COVENANTING

An interesting reference to the rite known as blood covenanting is made by Major C. Delmé-Radcliffe the officer commanding the Lango Field Force, in some despatches published in the *London Gazette* of Sept 12th When some of the chiefs, he says said that they wished to help us but dared not owing to the "blood brotherhood" a sufficiently ridiculous ceremony had to be gone through to free their consciences Dr A W G Bagshawe with due formalities injected a dose of apomorphia into the cicatrix of the incision made in the "blood brotherhood" rites This made the patient violently sick in about five minutes A few nauseous draughts afterwards completed the operation and the subject's satisfaction in the breaking of the spell. Mention is made of this curious rite in the writings of ancient authors and modern travellers. It takes many forms. In some cases the blood of the covenanters is merely allowed to mingle whether above ground or in a hole in the earth; in other cases the mingled blood is drunk Sometimes both persons and things are simply anointed with blood Stanley it has been stated in connexion with this rite has the blood of a fair proportion of the best families of Equatorial Africa in his veins

THE SPREAD OF PATHOLOGY AMONG THE MASSES

There was a mediæval distich to the following effect:

> Febris acuta, phthisis, pedicon scabies sacer ignis—
> Anthrax lippa, lepra, nobis contagia praestant "

From this it will be seen that the infectivity of phthisis has been known for some time. But the knowledge of this among the people had died out and it was not until lately owing in great measure to the efforts of the National Society for the Prevention of Consumption and other Forms of Tuberculosis, that the fact was realised. A remarkable instance of how the light is spreading was afforded by a case which came before the magistrate at the Westminster Police-court on Sept. 11th. Robert Clifton a paperhanger was summoned for travelling on the London and North Western Railway without a ticket The defendant pleaded guilty to travelling from Willesden to Sloane-square second-class with a workman s ticket. He said that he had done so from hygienic views as he was consumptive and believed in isolation Mr Francis, however, instead of being moved by this ingenious defence was hard hearted enough to inflict a fine and costs of 26s Mr Clifton will have to try again but we admire his brain power He must surely be a relative of the labourer who was charged the other day with being in unlawful possession of rabbits He was found with his pockets full of rabbits, but, according to him, he had lain down under a tree feeling tired The rabbits had run into his pockets and had suffocated themselves That was all he had to say

THE QUESTION OF THE COMMUNION CUP

We have received from Mr R C Oldfield of Liverpool a communicant s spoon designed with a view to prevent the danger of infection from the use of a common chalice Mr Oldfield s idea is that every communicant should dip his own spoon into the chalice To avoid the risk of accident the bowl of the spoon is covered in for about two-thirds of its area and it is set on to the handle at an obtuse angle Mr Oldfield doubtless means well and from a simply hygienic point of view his spoon leaves nothing to be desired, but in a matter of this kind hygiene is by no means the only thing to be considered

THE TREATMENT OF ASTHMA

To the Editors of The Lancet

Sirs,—Your correspondent "Rusticus' need not think that there is anything mysterious in Dr Tucker s atomiser A clerical friend of mine who had suffered from hay asthma all his life was loud in his praises of the relief he had obtained from this "cure I advised him to be careful as he was probably dealing with a potent drug which might have dangerous by-effects After some time my friend informed me that one day when his eyes were particularly troublesome he had sprayed them and he was astonished to find his pupils dilate and the sight become dim I replied that cocaine was in all probability the active constituent of the spray which he had used and cautioned him accordingly

There can be no doubt as to the value of cocaine in skilled hands, but it is worth noting that a chemist remarked to me recently that the majority of his cocaine customers had contracted the habit from using nasal sprays containing the drug

I am, Sirs yours faithfully,

Weymouth-street, W, Sept 13th, 1902. Chas W Chapman

DETAILED MEDICAL ACCOUNTS

To the Editors of The Lancet

Sirs —I think it the duty of every medical practitioner to render a detailed account when requested so to do It is easy if one has only method in his affairs I inclose for your benefit my system which is simple, time-saving and accurate In the space of four hours my bookkeeper can get through my books for the month enter every item, and give details, if need be of any account in a few minutes I claim for this method besides accuracy despatch and a saving in bookkeeper s wages My day book has left-hand margin, folio No name and address next a narrow column for whom attended Symbols are used as SF for head of family, M for Mrs S for son, Dr daughter, Cd child, Inft infant Next column visit next page ℞ £ *s* *d* The second book has name in full with address on left page with 31 spaces for the dates of the month, all of which are printed a spare column for entering total dates of attendance, as 5—15 Then follows £ *s* *d* and folio When all have been cast up they are entered in the ledger thus—Sept. 5—15, £1 3*s* 6*d* —I am Sirs, yours faithfully

Jas T T Ramsay L R C P, L.R C S Edin

Blackburn, Sept 15th, 1902.

To the Editors of The Lancet

Sirs —Your correspondent "Ledger" would do well to continue the present method of sending out accounts. As one who has been assistant and principal for 13 years in several large practices I can say that doing the books" is the most detested part of a medical man s work. The amount of work required in sending out 500 accounts every quarter is very great even with the present system, and your correspondent would find that having once commenced to send them out in detail he would be unable at a future date to discontinue it and so would be put to the expense of a bookkeeper A patient shows that he can trust one otherwise he would not come and my experience is that not 1 per cent wants a detailed account but if such is wanted I always give it with pleasure

I am Sirs, yours obediently,

Sept 13th, 1902. G P

THE USE OF THE TERM ENANTHEM"

Professor F Forchheimer of the Medical College of Ohio, U S.A, writing in the August number of the *Archives of Pediatrics* remarks that it is difficult to say by whom the term enanthem" was first employed he believes that it was first used by the French (Cadet de Gassicourt 1882) After this it was employed by the Germans In Eulenburg s ' Real Encyclopedie, edition of 1880 the word is not found but in the one of 1886 it occurs with a definition At the present time the term has been universally adopted by the French authors no modern description of the acute exanthemata exists in which it is not used. In Germany also the word is being made use of more and more constantly although Villaret s "Handwörterbuch der Gesammten Medizin" (1899) prefixes its definition by calling enanthem ' ein seltenes Wort (a rare word) Notwithstanding this in the latest of the larger works on practice of medicine—namely that by Schwalbe and Ebstein, vol v (1901)--the period of invasion in rubella is spoken of as the ' Stadium enanthematicum sive prodromorum" The word also occurs in the "Dictionnaire Encyclopédique des Sciences Médicales (1887) and in Littre In English it is found in the following dictionaries: Dunglison and Foster s medical dictionaries the Standard, the Century and the Imperial as enanthema, in Worcester as enanthesis always with the definition which seems the correct one The word ἐνάνθημα is not found in either modern or ancient Greek The word enanthem is interpreted by various authors in various ways Some claim that an enanthem is an exanthem upon the mucous membrane, the definition then resolving itself to the definition of an exanthem A second class of definitions of the term enanthem is the one represented by Villaret—namely "all efflorescences occurring on the inner surface of natural cavities—for instance, the nose the throat, the mouth, &c.—without pathological distinction"

OLD BOTTLES

A correspondent draws our attention to what he calls an abominable, disgusting, and dangerous practice' He refers to the use of second hand bottles by medical men and others such as wine and spirit merchants and pickle manufacturers He maintains that every bottle that has been used and thrown on one side for some time should not be used again but should be sold to old glass merchants and broken up and re-smelted We cannot see that the practice of using a bottle twice over is necessarily harmful There is no difficulty in cleansing a bottle or in sterilising it

"A QUERY"

To the Editors of The Lancet

Sirs —Your correspondent "Enquirer" in The Lancet of Sept 6th, p 720, probably alludes to Bérillon of Paris the Government Medical Inspector of Public Asylums, who treats morbid impulses, bad habits, masturbation, &c, by means of hypnotic suggestion claiming that these affections are very amenable to this method of treatment

I am, Sirs, yours faithfully,

James Shaw, M D R U I

Kensington, Liverpool Sept. 16th, 1902.

THE ENGLISH LANGUAGE IN EGYPT

The weekly statistical and meteorological return of the Egyptian Sanitary Department, which has been published in French under the title of *Bulletin Hebdomadaire* since 1885, is now drawn up in the English language, the change having been effected at the commencement of July last In other respects the form of the document has undergone no alteration.

◆

G S M —An old book, but a very good one is Southam s "Regional Surgery' Then there is Heath s "Surgical Diagnosis, written mainly for students With regard to medical diagnosis a small but useful book is Fenwick's "Medical Diagnosis" A book which our correspondent will find very helpful, though it is not exactly on the same plane as Medical Diagnosis is Judson Bury s ' Clinical Medicine,' published by Griffin and an excellent book, though a large one, is Butler's "Diagnostics of Internal Medicine," published by Kimpton

Lex —The answer depends very much on the size of the town in question In London for instance, a new-comer settles down without much notice being taken of his arrival, neither does he as a rule call on the neighbouring medical men But in a small town it is the custom for the newcomer to call on those already established in practice

D.P H —The newest work, and for our correspondent s particular purpose perhaps the best, is Hamer s "Manual of Hygiene (Churchill) but other good books are—Parkes and Kenwood s ' Hygiene" (Lewis) and Whitelegge s "Hygiene (Cassell)

Tunley —Our correspondent should apply to his local sanitary authority

Erratum —We regret that in an annotation which apppeared at page 759 of The Lancet of Sept 13th, owing to a printer's error the name of the writer upon whose paper we were commenting appeared as Dr Giuseppe Biller It should have been Dr Giuseppe Bellei

During the week marked copies of the following newspapers have been received —*Labour Leader, Hot Springs (Arkansas) Daily News, The Umpire, Dublin Evening Telegraph, Southampton Echo Belfast Guardian Lancaster Guardian, Bradford Observer, Sheffield Daily Telegraph, Echo, Daily Express, Standard Times, Windsor and Eton Express Globe Westminster Gazette, Derbyshire Times, Lincolnshire Echo Burnley Gazette, Reading Mercury Herts Advertiser Times of India, Aberdeen Free Press, Lancashire Post, Plymouth Morning News, Western Mercury, Devon and Exeter Express, Burnley Express Hackney and Kingsland Gazette, &c.*

Medical Diary for the ensuing Week.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* To THE EDITORS, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub-Editor '

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed To the Manager '*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s.* by post 2*s.* 3*d.*

To be obtained on application to the Manager accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM.	£	s.	d.	TO THE COLONIES AND ABROAD	£	s.	d.
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr CHARLES GOOD THE LANCET Offices, 423, Strand, London, W C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address— THE MANAGER, THE LANCET OFFICES, 423, STRAND LONDON ENGLAND.

Three Lectures
ON
SOME MORBID CONDITIONS OF THE MOUTH

Delivered at the Medical Graduates College and Polyclinic on Feb 10th, 17th and 24th 1902

By EDMUND W ROUGHTON, B S LOND, F R C S ENG,

SURGEON TO THE ROYAL FREE HOSPITAL AND HONORARY VISITING SURGEON TO THE NATIONAL DENTAL HOSPITAL.

LECTURE I.

Delivered on Feb 10th, 1902

GENTLEMEN —During the 10 years that I have been attached to the National Dental Hospital I have gained the impression that diseases of the mouth and more especially of the teeth are not so familiar to medical practitioners as they ought to be. No doubt this is largely due to the fact that the medical student receives no instruction in dental disorders. Of necessity the time which a student can devote to specialties during his curriculum must be small but this is to a certain extent remedied by the excellent custom of recently qualified men attending the practice of special departments or special hospitals I think that it is unfortunate that there are no facilities for the newly qualified man who is preparing for general practice to attend a short dental course, not, indeed with the object of becoming proficient in dentistry but to furnish him with a knowledge which I am sure would prove of great use in after life, more especially to those who are about to practise in country districts where expert dentistry is not obtainable This remark applies with even greater force to army and navy surgeons Another reason why dental disease does not receive the attention it deserves at the hands of the general practitioner is that there is a tendency amongst many medical men to regard dental disorders as the exclusive province of the dentist and as having nothing to do with medicine or surgery proper I hope to show that they have a great deal to do with many diseases which come almost daily under the care of the physician, the surgeon and the general practitioner

The Bacteria of the Mouth.

In studying the pathology of the mouth we are at the outset brought face to face with a great difference between this and many other regions of the body The mouth is a very perfect bacteriological incubator and as a natural consequence is at all times teeming with myriads of micro-organisms. For our knowledge of the mouth bacteria we are indebted chiefly to Professor Miller of Berlin, who has shown that very many varieties of organism both pathogenic and non pathogenic, may be found in the mouth he has isolated and cultivated more than 100 different species and has established the fact that the mouth is the receptacle and often the breeding ground of many specific organisms and is the source through which many serious, and even fatal, diseases may take place.

The conditions which obtain within the mouth are extremely favourable for bacterial growth. The temperature—viz. 37° C.—is that at which we keep our warm incubators in the laboratory sufficient access of air is afforded for those germs which require oxygen or are indifferent to its presence. Food materials (culture media) are present in abundance fragments of food remaining after a meal cast-off epithelial cells saliva, buccal mucus, inflammatory exudations from the gums, exposed pulps of teeth, and even dentine itself when decalcified, all serve as culture media for bacterial growth

With such favourable conditions and the frequent entry of germs into the mouth with air food, and drink it is little to be wondered at that so many organisms are constantly found indeed one might expect to find every germ in the bacteriologist's catalogue were it not for the fact that the struggle for existence is in operation here as elsewhere, causing the stronger to prevail and the weaker to perish. Thus it happens that although many species of bacteria may be at times found in the mouth the regular tenants are but few in number There are about six species of organisms which seem to find the conditions of the mouth exactly to their liking they flourish and crowd out all others Anyone possessed of an oil immersion lens and the most elementary knowledge of bacteriological technique may readily make acquaintance with these germs It is only necessary to scrape off a little of the white material which may be found on anyone's teeth before they are cleaned, spread it out in a very thin layer on a cover glass, stain with gentian violet, and examine it under the microscope. Amongst the many bacterial forms presented to view the attention will be first arrested by the rod-shaped organisms, most of these are in the shape of long jointless filaments somewhat resembling a tangled bunch of string and usually known under the somewhat inclusive name "leptothrix." Sometimes they assume comparatively gigantic proportions, many long wavy filaments being attached to a common root of structureless material. Jointed bacilli will also be seen in abundance, noticeable amongst them being the bacillus buccalis maximus occurring in long thick rods. When treated with dilute iodine solution the bacillus is stained violet. Micrococci although perhaps as numerous are on account of their smaller size less conspicuous than the bacilli and threads. They are sometimes in clusters, sometimes in pairs, tetrads, or chains or scattered singly A further search will reveal the presence of spiral organisms morphologically identical with Koch's cholera vibrio; these are especially abundant if the specimen has been taken from the neck of a tooth near an inflamed gum. So close is the resemblance between this organism and the cholera vibrio that when Koch first announced his discovery Klein discredited it by asserting that he had found the same organism in his own mouth. Further experience showed that, although morphologically identical their culture characters were widely different, and that whilst the cholera vibrio could be readily grown on the ordinary culture media the common bacillus of the mouth refused to grow outside the oral cavity Vicentini has attempted to prove that the various forms of mouth bacteria are all different phases of one organism which he terms leptothrix racemosa" but there is no need for us to pursue the subject into realms of purely scientific interest. It is of more practical interest to inquire what is the result of the presence of bacteria in the mouth. Do they do any good? Do they do any harm? The first question has not been as yet fully answered, but it is probable that they take some share in the process of digestion. That these bacteria may do harm is well known. I propose in these lectures to deal with some of the morbid conditions which they produce.

Dental Caries

Foremost amongst these on account of its frequency if not of its importance, is dental caries, a disease which is of almost universal distribution. Evidences are not lacking that prehistoric man suffered from dental caries and alveolar abscess. Many of the Egyptian mummies in our museums show well marked evidence of caries and other diseases of the teeth. The Egyptians had doctors for the eyes for the ears, and for the teeth and forceps for dental extraction may be found amongst museum collections of Egyptian antiquities. The early Greek physicians paid much attention to diseases of the teeth and during the latter part of the Greek epoch the young men of fashion gave great attention to their teeth and were proud of having them fine and white, although their more athletic brothers regarded such attention to personal appearance as effeminate and only suitable to women and fools Dr Schliemann during his excavations at the site of ancient Troy found several crania with carious teeth some of them even stopped with metals, especially lead. The researches of Mummery and others amongst ancient crania have shown that the prevalence of caries bears a very close relationship to the degree of civilisation and the luxurious habits indulged in by the ancients Thus in ancient Britons of the dolichocephalic type 3 per cent. had caries, whilst of the brachiocephalic type, 22 per cent. Romano-Briton 29 per cent. and ancient Egyptians, 42 per cent Miller maintains that caries is less prevalent in meat-eating races than in those which subsist upon mixed foods This accords with the statement just given and is borne out by investigation amongst the modern aboriginal flesh-eaters caries being rare amongst the North American Indians Fiji Islanders New Zealanders and Lapps whilst the Icelanders seem to be almost free from the disease

Amongst the civilised nations of the present time there are no statistics which definitely determine the frequency of caries, but there can be no doubt that the percentage is a large one and it is apparently on the increase. It is generally conceded that caries is more common amongst women than amongst men in the proportion of roughly three to two, and that married women are more liable to it than spinsters, the period of pregnancy and lactation being especially favourable to the development and progress of the disease. "For every child a tooth" is a well-known adage. A good idea of the prevalence of dental caries is afforded by the report of the School Commissioners of the British Dental Association who examined 3368 boys and girls at the Hanwell and Sutton Schools and on board the *Exmouth* training ship. They found that 23 per cent. had sound dentures, whilst the remaining 77 per cent. had at least one carious tooth. A similar investigation amongst 19,725 German school children belonging to 19 towns revealed caries in 95 per cent.

It is interesting to note the wide difference existing in the relative frequency of the disease in the upper and the lower jaw and between individual classes and groups of teeth. The right and the left sides are about equally affected, whilst the upper teeth are more often carious than the lower in the proportion of nearly two to one. The first permanent molars are the most often decayed, whilst the lower central incisors are so rarely carious that they may be almost considered immune. The cause of this irregular distribution has not been worked out.

There are many causes which predispose the teeth to decay. The influence of civilisation has been already referred to. The environment of the civilised man tends to lower the development and vital resistance of the dental structures which is found in such perfection amongst savage races. Structural defects in the enamel, the result of constitutional conditions which have impaired nutrition, are a most important factor in predisposing the teeth to caries. The most noticeable of these defects are the pits or honeycombed conditions, grooves, and absence of enamel which are so often seen in the subjects of inherited syphilis and in those who have been treated with mercury during childhood. Less noticeable but infinitely more common are the sulci or fissures formed by the union of developmental lobes, which may be found in almost all teeth, even the most perfect. These conditions invite the establishment of caries by making it possible for micro-organisms to find a lodgment where they can propagate undisturbed. Many of these enamel defects are so minute as to be discoverable only on microscopic examination, yet they suffice to initiate decay. Traumatic defects in the enamel play the same rôle, but not to the same extent. Injuries which fracture the enamel, leaving the dentine exposed, if occurring at points which are subject to the friction of mastication, rarely develop caries, but injuries which result in splitting of the enamel without much displacement are often followed by decay since they afford a suitable lodgment for bacteria.

In the normal dental arch the teeth are wider at their biting surfaces than at their necks, thus leaving between adjacent teeth a V shaped interspace which is readily kept clean by the flow through them of the fluids of the mouth as well as by artificial means. Any alteration in the shape or arrangement of the teeth which partially obliterates these interspaces favours the lodgment of alimentary débris and the development of bacteria.

Abnormal conditions of the oral secretions play a not unimportant part in the causation of caries. Normal mixed saliva has generally an alkaline reaction, but buccal mucus is acid; it thus happens that inflammatory conditions, such as stomatitis, gingivitis, &c., by augmenting the secretion of buccal mucus render the saliva acid. Acidity of the oral secretions is not uncommon during the exanthemata and other febrile conditions as well as during pregnancy and lactation.

It would serve no useful purpose to review the different theories of decay which writers from the very earliest ages have advanced. At the present day the germ theory (chiefly through the researches of Miller) occupies an unassailable position. It is generally agreed that the mouth bacteria are the direct cause of dental caries, that certain of them possess the property of forming acids (chiefly lactic acid) which acting upon the lime salts of the enamel, disintegrate it and thus permit the entrance of organisms into the dentinal tubules, where they continue the process by dissolving the lime salts from the dentine and that afterwards certain other bacteria liquefy, peptonise, or digest the basis substance, thus removing the organic tissue and forming a cavity of decay.

The first stage, then, of caries is disintegration of the enamel; this tissue contains no organic matrix and is completely dissolved by weak acids. In the mouth lactic acid is generated from carbohydrate food by the action of certain zymogenic bacteria which adhere to the teeth in zoogloea masses. The acid attacks the interprismatic substance first, causing the enamel rods to fall apart and expose the underlying dentine, which in its turn becomes decalcified. The decalcification of the dentine is followed by invasion of the dentinal tubules by micro organisms of different kinds; cocci, bacilli, and spiral threads may all be seen in the same specimen, although not often in the same tubule. In the deeper layers of decalcified dentine the bacteria become less and less in numbers until they finally disappear. Beyond this non infected line there is a zone of partially decalcified dentine, the removal of the lime salts being caused by the solvent action of the lactic acid produced by the bacteria lodged within the tubules. Generally the line of progress or penetration of caries is in the direction of the tubule so that sooner or later, if the process is unchecked, the pulp is involved and becomes inflamed. This inflammation may subside either spontaneously or under suitable treatment but may proceed to ulceration, suppuration, or gangrene of the pulp and death of the affected tooth. Thus the process of destruction of useful organs goes on and the function they should perform is necessarily impaired.

Although there are many people whose mouths are destitute of teeth or full of carious stumps but who yet never suffer from indigestion, it must be obvious that dental disease, by impairing the function of mastication, must throw additional work upon the stomach. The physician makes it a rule to look at the tongue of his dyspeptic patient, but I fancy he very often neglects to see whether his teeth are in proper working order. I wonder how many cases of dyspepsia are treated annually in our hospital out-patient rooms with a mixture of gentian and rhubarb or a similar prescription when the proper treatment is really a new set of teeth. In every case of indigestion the condition of the teeth should be ascertained, the presence of carious teeth should be noted, and where teeth have been lost it should be ascertained whether those which remain can perform the function of mastication. Sound teeth which have no fellows to bite against are useless for purposes of mastication.

PAIN IN DENTAL DISEASE.

Of the symptoms or effects of dental caries that which is best known and most generally recognised is pain; most people know what toothache is, but there are many people, including medical men who do not form a correct estimate of the relation of pain to dental disease. To say that a diseased tooth may ache is to state the truth, but by no means the whole truth. Practically any disease of a tooth may produce toothache. The dentinal tubules contain minute processes extending into them from the cells of the pulp; it is uncertain whether these processes are of the nature of nerve fibrils, but it is well known that exposure of dentine by erosion or decay may produce pain or, at any rate, undue sensitiveness. When destruction of dentine exposes the pulp severe pain is common.

It is well known that extensive dental caries may be present without toothache or pain of any kind, especially so long as the person is in good health; but it not uncommonly happens that diseased teeth, previously the seat of little or no pain, are prone to ache when the patient has become lowered by disease or exhaustion or when the buccal secretions become vitiated by dyspeptic derangement or in pregnancy. As a general rule, the pain is felt in the diseased tooth, but not always—it is quite common for a patient to refer the pain to a neighbouring tooth which may be quite sound. I well remember when I was a dresser a man coming to the surgery complaining of toothache and wanting the aching tooth extracted. He had a carious molar, but he referred the pain to the next tooth which appeared perfectly sound. I was for taking out the decayed tooth but the man would have it that the sound one ached; thinking that he probably knew best I pulled out the sound one. I do not know what the result was for I never saw the man again; perhaps it was as well for me I did not.

This transference of pain from a decayed tooth to a sound one is no doubt of the same nature as the pain so commonly felt in the knee in cases of hip disease, but owing to the complexity of the fifth nerve the transference may be much more varied or remote. Disease of a tooth may cause toothache in the other jaw or the pain may be referred to a region remote from the mouth. In my experience much the commonest instance of this is pain in the ear in connexion with carious lower molars. I frequently see patients who come complaining of earache and on examining the ear I find nothing whatever wrong On looking into the mouth I invariably find carious molar teeth, nearly always lower molars but occasionally uppers. Proper dental treatment cures the earache.

Pain extending more or less all over the side of the face is very commonly associated with well marked toothache, but we not unfrequently see this same pain due to dental disease but without any pain in the tooth. With the general public (especially the feminine section) this is neuralgia" and not toothache, and is to be treated by drugs and not by a visit to the dentist. It is sometimes difficult to persuade such sufferers of their mistake. A medical friend once consulted me for severe facial neuralgia he admitted that he had a bad tooth but declared it did not ache. After some persuasion he consulted his dentist. The process of killing the nerve of the tooth which did not ache was attended by severe pain all over the neuralgic area, but it effected a speedy and effectual cure Such cases might be multiplied indefinitely

It would appear that although referred pain in dental disease is usually limited to the area of distribution of the fifth nerve it may occasionally extend to other regions. Thus Salter records the case of a patient who suffered from neuralgic pains in the arm apparently due to carious teeth When any one of the teeth in the lower jaw on the left side became irritable or tender from caries she was immediately attacked with severe neuralgic pain at a spot small and circumscribed on the front of the left forearm, about two inches below the line of flexure of the elbow joint, and what is more remarkable is that when her artificial teeth hurt the lower jaw on that side the same symptom manifested itself The right side has never been similarly affected. Another female patient applied to Sir S Wilks for relief from a constant aching pain on the left side of the face and neck and left arm. The pain sometimes became intensely severe The arm had nearly lost all muscular power the patient could not raise it to her head or squeeze any object in her hand. This state of things had existed for two years and the patient had been under medical treatment all the time. Upon examining her mouth a carious left lower wisdom tooth was discovered. After this was extracted she immediately felt great relief and in a few hours all her symptoms had completely disappeared.

Many writers have recognised the teeth as one of the causes of headache. Lauder Brunton says My attention was first directed to the relation between pain in the temple and decayed teeth many years ago A servant was suffering from toothache but complained still more of intense pain in the temple I did not know what to do for the pain in the temple, but I thought the toothache might be relieved by applying solid carbolic acid on a pledget of cotton wool. I accordingly introduced this into a large cavity in one molar To my great disappointment it gave no relief whatever In the course of a very few minutes her fellow-servants came running to tell me that the cook was now quite free from pain, that she had taken the cotton wool out of the tooth into which I had placed it, and put it in another decayed tooth and at once the pain vanished both from the tooth and from the temple In this case the irritation of a decayed tooth had produced a two-fold pain—a pain felt in the tooth itself and also one felt in the temple but sometimes a decayed tooth will cause headache when no pain is felt in the tooth itself." Brunton was led to observe this by watching his own case One day he was suffering from severe migraine, the pain being limited to the left temple. On percussing his teeth he found that every one was sound excepting the last molar on the same side as the headache. This proved to be carious He also refers to the case of a clergyman who suffered from intense headache unrelieved by various medicines and visits to continental health resorts. A tender tooth was discovered and found to be carious This was stopped and the headaches disappeared. Brunton is of opinion that headaches are very frequently of dental origin and always commences his investigation of a case of headache by carefully examining the teeth He states that a decayed lower molar usually causes a temporal or occipital headache a decayed upper molar headache which is rather further forward than that caused by the lower jaw, whilst decayed incisors or canines are more likely to cause frontal or vertical headache. Although I do not myself believe that headache is so frequently of dental origin it should be borne in mind that it may sometimes be so and in any obscure case a careful examination of the mouth should be made.

As a general rule the recognition of the nature of a case of remote dental pain is not difficult provided that one bears in mind the possibility of its occurrence and takes the trouble to examine the teeth. But the diagnosis is not always easy a careless or inexperienced observer may examine a set of teeth and pronounce them healthy when an expert might detect quite sufficient to cause the pain Each tooth should be examined separately Cavities hidden in the interstices or below the gum must be sought for A fine dental probe carefully passed over the neck and hidden surfaces of a tooth will often discover a cavity having perhaps only a small aperture but passing deeply towards the pulp The teeth should be percussed with a steel instrument a sharp tap on the masticating surface will often reveal abnormal sensitiveness and so lead to detection of the offending tooth A stream of cold water from a small syringe is a useful test for sensitiveness. Decayed or broken down wisdom teeth are often difficult to discover In the upper jaw they may be invisible except with a mouth mirror whilst in the lower jaw they are commonly hidden by folds of cheek or overhanging gum. Decaying in many instances before they are completely erupted these teeth after the destruction of their crowns by caries are occasionally quite invisible and their presence in the sockets can be ascertained only by passing a probe through the small fistulous track in the gum which covers them. A condition similar to this may exist in the case of any other tooth, and buried roots especially when exostosed are often exciters of neuralgia. Impacted lower wisdom teeth even when free from decay sometimes cause intense neuralgia by pressing directly upon the adjacent trunk of the inferior dental nerve Sewell records a case of severe neuralgia in which he extracted the lower wisdom tooth and found that the inferior dental nerve had traversed a foramen in one fang and a deep groove in the other complete anæsthesia of the parts supplied by the nerve immediately followed the operation but sensation slowly returned in the course of months. The most difficult cases to diagnose are those in which isolated nodules of secondary dentine occur in the pulps of externally healthy teeth. Such a condition may cause severe neuralgia and can only be recognised after the tooth has been extracted and split open Although dental disease is a very common cause of facial neuralgia it must be remembered that there are other diseases which may involve the fifth nerve and cause toothache although there is no dental disease. As an example I may cite Bland Sutton's well known case of a woman who was supposed to be suffering from neuralgia due to bad teeth. A careful examination detected anæsthesia of the side of the nose and the lower lid, with a slight displacement of the eyeball. The superior maxilla was removed and a myxomatous tumour was found springing from the infra orbital nerve and filling the antrum and invading the orbit.

In acute inflammation of the antrum severe toothache and facial neuralgia are common especially when temporary blockage of the ostium maxillare leads to retention of discharge under pressure. In such cases even teeth which have long since been extracted may appear to ache. This is doubtless due to involvement of the superior dental nerves. In chronic empyema of the antrum pain is not common and when present is often in the supra orbital region and may lead to a false suggestion of disease of the frontal sinus. Syphilitic nodes foreign bodies, exostoses necrosis or other lesions involving some part of the fifth nerves might be added to the list of diseases causing healthy teeth to ache or to seem to do so Lastly there are cases of toothache and pain in other parts of the distribution of the fifth nerve not due to any discoverable organic lesion of teeth nerves or other parts It is for these cases that in my opinion the term neuralgia should be reserved pain in a tooth the result of dental disease should be called toothache pain in a remote part due to dental disease should be called remote toothache and when our inability to fathom the nature of a case compels us to call it neuralgia we should not flatter ourselves that we have made a diagnosis but should recognise that our diagnostic skill is inadequate

REFLEX NEUROSES OF DENTAL ORIGIN

I now come to a branch of my subject which is of a more speculative character, the so called dental reflexes No one can deny that the different tissues and organs of the body are to a large extent inter-dependent upon one another and that disease of one part may produce symptoms or disturbances in a remote region. It may be conceded that to a certain extent these effects are produced through the medium of the nervous system and perhaps more particularly through the sympathetic. It is common knowledge that an offensive odour may produce vomiting, that cough may be due to a plug of wax in the ear, that a bright light or even syringing the eye sometimes causes sneezing, and that the uterus contracts when the infant is put to the breast These phenomena are undoubtedly due to nervous action , no other explanation is possible. Unfortunately, a knowledge of these undoubted reflex neuroses has led many writers to attempt to explain away many obscure symptoms and conditions most of which probably have nothing to do with the nervous system The sympathetic system is their sheet anchor, and they seem to think that the chief function of these imperfectly understood nerves is to produce pain in the wrong place and to lead the practitioner away from the true scent in his hunt for the seat of disease The specialist is usually the worst offender in this respect and it may be remarked that he does not usually try to refer symptoms in his own little sphere to disease in distant parts that he is not accustomed to operate on. The sins of the ardent rhinologist have been recently dealt with by Semon and I hope that one effect of his lectures and the correspondence which followed will be to make the armchair pathologist cautious in his exploitation of the sympathetic system. As far as my experience and reading go the dentist is not prone to over-estimate the remote effects of dental disease, the records of so called dental reflex neurosis being from the pens of practitioners in other branches of the healing art. It is, however, an undoubted fact that reflex spasm may be due to dental disease I have frequently seen cases in which trismus or inability to open the mouth was dependent upon spasm of the muscles of mastication due to an impacted lower wisdom tooth Owing to want of room between the second molar and the ramus of the jaw, or owing to some malposition of the tooth itself, the wisdom tooth is unable to assume its normal position, and by the pressure it exerts on neighbouring structures sets up irritation which induces a state of tonic spasm of the masseter, pterygoid, and temporal muscles Many such cases are on record Tomes records a case of retarded eruption of a wisdom tooth with closure of the jaws which had been allowed to go unrelieved for two years It was immediately cured by removal of the second molar so as to allow the wisdom tooth to assume its proper position. Although many, perhaps most, of the cases are reflex spasms, it must not be assumed that all of them are for it is not uncommon for inflammation starting around an impacted wisdom tooth to extend to the adjacent muscles , as a rule this myositis subsides as soon as the inflammatory mischief ceases, but it may lead to a permanent contraction.

Although muscular spasm may certainly be of dental origin it appears very doubtful whether paresis or paralysis is ever due to the same cause. There are, however, many cases on record in which so-called reflex paralysis is attributed to dental disease Thus Gillman, Evarts, and Coale each record a case of facial paralysis due to carious teeth, Whitney relates a case of paralysis of the arm from dental irritation, and Salter gives a case of paralysis of the arm from an impacted and carious wisdom tooth, and others might also be cited. But although the paralytic conditions are usually said to have disappeared after dental treatment it seems to me very difficult, if not impossible, to prove that they were due to the teeth and not really of the nature usually designated "hysterical"—whatever that may be

Many cases of ophthalmic disease supposed to be due to diseased teeth are on record Pain in the eye and excessive secretion of tears may certainly be due to dental irritation, but so far as I can discover there is no authentic case which definitely proves that any actual eye disease is really a reflex dental neurosis The nearest approach that I can find is the case recorded by Mr H. Sewill in his work on Dental Surgery A middle-aged woman suffered from bad teeth and neuralgia. In 1880 she began to notice pricking pains in her eyes, and in 1882 contraction of the muscles of the right side of the face , six months later she lost the sight of the right eye which had become cataractous. She had many carious teeth, much tartar, and much swelling and inflammation of the gums After appropriate dental treatment the facial spasm slowly subsided, and with the exception of the cataractous eye she made a complete recovery Mr Henry Power believes that carious teeth are a common cause of phlyctenular ophthalmia , the two conditions, however, are so common that it would be strange were they not often associated He also records a case of neuro paralytic ulcer of the cornea which he attributed to dental irritation, but although some improvement followed extraction of the diseased teeth the eye had to be subsequently removed. Blake records a case of internal squint in a child, aged five years, with "sadly carious teeth." He diagnosed reflex paresis of the left abducens due to dental caries *viâ* Meckel's ganglion Two years subsequently he heard that there had been a progressive improvement in the axis of the left eye since the removal and stopping of the erring teeth. The report of the case is the reverse of convincing Sir W J Collins who has devoted much attention to oculo-dental affections asserts that he knows of no case of ophthalmoplegia of any kind due to dental disease

Many cases of reflex amblyopia are on record , here is one which I cull from a volume of the Transactions of the Odontological Society A girl, aged 15 years, suffered from failing vision and became, according to her own account, blind in a week , her pupils were dilated and insensible She had two teeth taken out and "her vision returned to her when walking away from the hospital " A week previously to this miraculous cure this blind girl had been examined by a well-known oculist who after some persuasion made her read $\frac{6}{6}$ with either eye and designated the case "hysterical amblyopia." The recorder of the case nevertheless prefers to consider it a case of "reflex blindness " On the next page he quotes the case of a totally blind girl who shrieked when a frog was suddenly displayed before her eyes He is content to call this a case of "hysterical amblyopia "—I presume because no carious teeth were noted or extracted Another author cites a case of a woman, aged 45 years, who complained of impaired vision in the right eye and a painful right upper bicuspid. On closer questioning he found that the trouble was a suddenly increased presbyopia in the right eye The offending tooth was removed and the failure of accommodation was restored He does not state that he had been careful to exclude the possibility of the failure of accommodation being due to the accidental introduction of atropin, nor does he state whether the patient had been wearing a belladonna plaster It must be admitted, however, that there are some cases on record in which the association between dental disease and amaurosis is to say the least remarkable Dr De Witt reports the following case "A merchant, aged 31 years, of good constitution and health always excellent, in June, 1856, whilst in the act of firing a gun, first discovered that he was blind in the right eye He had no pain in the eye at the time or subsequently Vision was lost without his being able to ascribe it to any cause In this condition the eye remained for nearly 12 years; he could merely discriminate light from darkness On Dec. 24th, 1867, I inquired as to the condition of his eye and endeavoured to ascertain the probable cause of the malady I learnt that two months before his loss of sight he had several teeth filled Upon examination I found a large cavity in the first bicuspid of the right upper jaw which had been neatly filled There was also a fistulous opening upon the alveolus opposite that tooth. I advised its extraction but the patient being naturally very timid objected. I then removed the filling by which I hoped the irritation might be relieved The fistula closed and vision was gradually restored. About three weeks subsequent to this, when the eye had become nearly as good as its fellow, the soreness of the gum returned and vision simultaneously became blurred A week later I extracted the tooth when the blur immediately disappeared At the present time (January 1868) the patient can see quite as well with the right eye as with the left."

Many diseases of the ear have been attributed to dental disease but I think without sufficient evidence Epilepsy, mania, delusions, and other nervous disorders, including neuroses of the alimentary canal, larynx, heart, and uterus, as a sequel of dental irritation have from time to time been described by writers When I say that amongst the list may be found cases of vicarious menstruation and urethral catarrh you will probably agree with me that I have pursued the subject far enough

THE RADICAL TREATMENT OF CHRONIC INTESTINAL TUBERCULOSIS, WITH SUGGESTIONS FOR TREATMENT IN MORE ACUTE DISEASE AND IN TUBERCULOUS PERITONITIS[1]

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
VICE-PRESIDENT, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following cases of chronic tuberculous disease in the intestine treated surgically have raised hopes in my mind as to the possibility of doing good not only in chronic cases such as are here related but in some more acute cases where if the disease be strictly limited a radical operation might remove it, but where if more extensive a short-circuiting might set the part at rest and relieve it from irritation, thus enabling the ulcers to heal, the surgical measures being supplemented by general, medical, and hygienic treatment. Whether these hopes will be realised or not I trust that the cases in themselves may prove of sufficient interest to warrant me in bringing them to notice. I think my readers will agree that whatever may be their views on the treatment of acute intestinal ulceration, in chronic intestinal tuberculosis especially if associated with stricture, surgical treatment is advisable.

CASE 1. *Tuberculous disease of the appendix extending to the cæcum and ileum; stricture of the ileo-cæcal valve; removal of the cæcum and adjoining part of the ileum and ascending colon.*—A man, aged 23 years, was sent to me on June 19th, 1900, with the history that after symptoms pointing to chronic appendicitis an operation had been undertaken by an experienced surgeon who found tuberculous disease of the appendix without any general affection of the peritoneum or glands, but as there were numerous adhesions and some matting of viscera in the neighbourhood the appendix was not removed and the abdomen was closed. The patient was in no way relieved and steadily grew worse generally and locally. When I saw him he was very thin and gave the history of having had pains in the cæcal region for 18 months, associated at times with paroxysmal pain extending across the abdomen, the paroxysmal attacks having recently become very frequent. There had been great loss of flesh with night sweats and diarrhœa. A hard swelling could be felt in the cæcal region and a coil of intestine below the umbilicus could be felt to contract and to harden under the examining hand, indicating chronic obstruction.

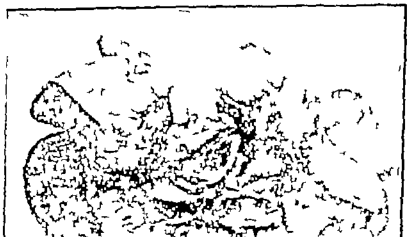
Operation was performed on July 17th, 1900. An oblique incision along the outer border of the right rectus was made. There was miliary tubercle on the peritoneum with slight serous effusion, also considerable matting of the viscera adjacent to the cæcum. The tumour, consisting of the cæcum, the lower third of the ascending colon, the appendix, and several inches of ileum, was removed and the open end of the ileum was connected to the ascending colon by means of continuous sutures applied over a decalcified bone bobbin. On account of adhesions it was difficult to explore the rest of the abdomen, but no other mass could be discovered and the mesenteric glands, except those in the vicinity of the lower end of the ileum, were apparently not involved. The wound healed by first intention and the sutures were removed on the seventh day, but on the tenth day a small purulent collection was evacuated from the lower end of the scar and the length of time that the slight sinus took to heal suggested tuberculous infection. He returned home on August 29th markedly improved in his general health. Fresh air and general tonic treatment were advised. On June 3rd, 1901, nearly a year later the medical superintendent of a Durham sanatorium wrote to me to say that the patient was improving generally but that he had had some abdominal pain suggestive of obstruction by a constricting band. A further exploration to ascertain if there are any bands or other removeable cause of obstruction has not yet been pressed as it has not appeared to be absolutely necessary and the general health has improved.

The mass removed showed tuberculous ulceration with great thickening of the cæcum and ileum, the disease having apparently started in the appendix and then extended to the cæcum and involved the ileo-cæcal valve, which would barely admit the tip of the little finger.

CASE 2. *Multiple tuberculous strictures of the ileum; enterectomy.*—For the history of the following cases I am indebted to my dresser Dr. J. Acomb. The patient was a woman aged 51 years, who was seen with Dr. R. Petch of York. With regard to the family history, on the father's side it was negative but on the mother's side it was decidedly tuberculous. As to her previous history she appeared to overgrow her strength between the ages of 10 and 14 years. When 10 years old she had a glandular swelling in the neck which was incised. She had no cough until 12 or 13 years ago, since which time she had been troubled by bronchial catarrh every winter. There was no perspiration at night. She had recently lost flesh and strength very considerably. For some 15 to 20 years the patient had suffered from so-called "bilious" attacks accompanied by vomiting and pain across the abdomen which would pass away after a few hours with diarrhœa. She was of a bad colour at the time of the attacks but had no apparent jaundice. These attacks occurred for some years, with perhaps a month's interval between each. Five years ago the character of the attacks appeared gradually to change and three years ago their place was taken by a constant pain across the waist and back. The pain did not radiate and was accompanied by indigestion and flatulence. She was subject to attacks of constipation for two or three days, followed by diarrhœa for three or four days, which would be accompanied by griping pain and would come on quite suddenly and unexpectedly. No distension was noted; there was no tenderness during the intervals of pain and no tenesmus; the stools, as a rule, were watery. There was slight bleeding from the bowel on defecation five or six years ago but no blood had been noticed since. When seen by me on July 22nd, 1901, the patient was very thin and it was easy to see vermicular contraction of the intestines, the tumour coming and going at varying intervals, the pain being at times very severe. On examining by the rectum a nodular growth could be felt in Douglas's pouch which was quite moveable from side to side and could be pushed out of reach. Operation was advised and was performed in York on July 26th.

The abdomen was opened in the middle line and the tumour previously felt by the rectum was discovered to be a coil of intestine very much thickened and forming a mass as shown in the illustration (Fig. 1), there being no less than four distinct strictures, the first within one and a half feet of the last and all in the ileum. The affected area was brought through the incision, surrounded by sterilised gauze and excised, the healthy bowel being sutured end to end over a decalcified bone bobbin.

FIG. 1.



Tuberculous disease of the ileum with multiple strictures and enlarged glands.

I have not seen the patient since but have heard that she recovered from the operation and gained flesh and strength.

---

[1] A paper read before the Clinical Society of London on Jan. 10th, 1902.

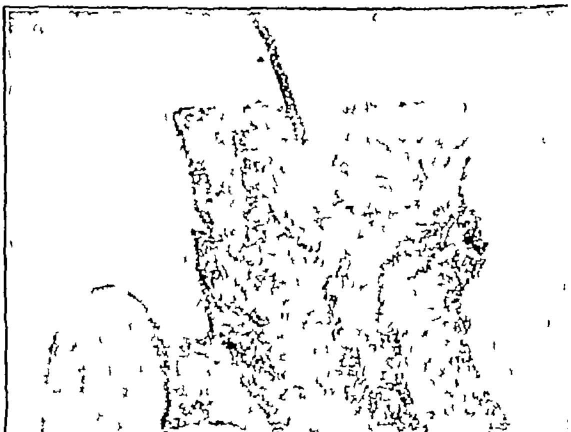
A year later she was well in every respect The specimen removed was examined by Dr Norman Smith, pathologist to the Leeds Infirmary, who gave the following report "There is a great increase of small round leucocytes and of connective tissue in the submucous layer At places the leucocytes form dense, deeply-stained aggregations Seen by the higher powers they are made up of peripheral parts composed of small cells and a central portion of large cells They are apparently giant cell arrangements At places in the muscular coat the same arrangement is commencing to be formed " The diagnosis was chronic tuberculosis of the bowel The specimen is an extremely interesting one as showing how near to stenosis it is possible to get without complete obstruction, it also shows a gall stone entangled in a pouch between two of the strictures

CASE 3 *Multiple tuberculous strictures of the ileum, short circuiting*—The patient was a woman, aged 20 years, whom I saw with Dr J G E Colby of Malton on March 6th, 1901 She gave the history that she had always been weak and thin since the age of 10 years but this was accounted for by her having grown so rapidly At the age of 15½ years she began to have pain in the abdomen on the right side associated with diarrhœa two or three times a day From that time onward she had never been long free from pain and diarrhœa and lately her attacks were coming on with greater frequency Her loss of flesh and weakness was very marked and she suffered from night perspirations No tumour had been discovered and she had not been troubled with vomiting The motions contained neither blood nor slime, but were, as a rule, quite fluid, like water The pain came on directly after food for five minutes, then passed away, and two hours later diarrhœa usually followed. On examining the abdomen there were a rigid right rectus and tenderness in the cæcal region, but no swelling could be felt Stricture was diagnosed and operation was advised Although she tried fully various forms of medical treatment with careful dieting and plenty of fresh air there was no improvement and on June 10th I operated on her at a surgical home in Leeds The ileum was found to be strictured in several places and the bowel generally was thickened over a distance of two feet before its termination in the cæcum Miliary tubercles were scattered over the affected bowel and the adjoining mesentery, but the abdomen was not generally invaded by tubercle There was some free fluid in the peritoneal cavity As the patient was so very feeble it was thought that she would not survive the removal of so much as two feet of the bowel, short-circuiting was therefore performed, the ileum being connected to the transverse colon by means of a decalcified bone bobbin The wound healed by first intention and the patient was sent home to the country on July 4th, and a very good report has been received of her progress It was intended that she should return in order to have the diseased bowel excised, but her gain in health and the relief from the diarrhœa have made her shy of facing any further operation which I think may not be necessary She is now said to be in good health

CASE 4 *Stricture of the duodenum probably tuberculous, associated with tubercle of the stomach and stenosis of the pylorus*—The patient, a feeble girl, aged 19 years, was seen in 1895 She only weighed 4 stones 10 pounds and gave a history of vomiting and pain after food for four years though the loss of flesh had only been very pronounced during six months She was deathly pale and was so thin that the skin was tightly stretched over the bones Tuberculous glands were felt in the neck. The abdomen was swollen The stomach was markedly dilated. On opening the abdomen the pylorus was found to be thickened and covered with tuberculous nodules which were scattered over the omentum and other viscera Some free fluid was found in the peritoneal cavity On laying open the pylorus to perform pyloroplasty the finger was passed into the duodenum and encountered a stricture one inch beyond the pyloric ring, this was evidently the result of ulceration The tip of the little finger could just pass through it. A Weiss dilator was employed to stretch the stricture which was dilated so as to allow the thumb to pass readily through it The pyloric incision was then closed by sutures transversely to the axis of the canal. For a week the after-operative progress was satisfactory, the wound healed and the stitches were removed, but no strength was gained and she gradually failed and died from exhaustion in the second week. With my present experience I should have performed gastro enterostomy and begun feeding at once and I believe the result would have been different

CASE 5 *Tuberculosis of the cæcum, enterectomy*—(This report was furnished by Mr J F Dobson, resident surgical officer) The patient, a woman, aged 22 years, was admitted to the Leeds Infirmary on Nov 15th, 1897 The patient had suffered from dyspepsia for several years About six months previously she noticed that her side was painful when she turned and that she could not bear the pressure of her stays This became worse and was accompanied by attacks of rather acute abdominal pain, principally in the right side She never vomited during the attacks and had never been jaundiced The pain had no relation to meals The bowels were regular, generally rather loose, no blood or mucus was noticed The appetite was poor and there had been considerable wasting of late Menstruation commenced at 17 years of age, lately it had been scanty and painful The tumour was felt in the region of the cæcum but tenderness was not marked At the operation the tumour was found to involve the cæcum and the commencement of the ascending colon The lumen of the gut was not occluded but narrowed. No general tuberculosis of the peritoneum was observed and no enlargement of the glands was found The tumour was excised and the ileum and ascending colon were united by continuous sutures over a decalcified bone bobbin The wound healed kindly and the patient improved rapidly and was discharged in fair health on Jan 8th, 1898 Although the health was regained and there was no further return of the abdominal trouble the patient had pleurisy some months afterwards and is said to have died nearly a year later at her home The pathologist's report was that a portion of tissue removed from the wall of the cæcum was of a pale grey colour, fairly elastic and translucent. Microscopically, delicate fibrous tissue with a few round and spindle cells between was seen Many rounded and oval areas occurred where collections of round cells were tightly packed In the midst of each group one or more well developed giant cells were found. Appended is an illustration of the specimen removed at the operation (Fig 2)

FIG 2.



Tuberculous disease of the cæcum

CASE 6 *Tuberculous disease of the rectum and sign flexure of the colon, colotomy and partial colectomy*—A m aged 37 years, was admitted to the Leeds Infirmary Oct. 31st 1898, suffering from a profuse purulent discha from the anus associated with great pain, which increased defecation, and with diarrhœa and great deterioration health. He gave the history of having had an operation "fistula in ano" three years before, from which recovered but six months later he noticed the motions to be streaked with blood and slime which gradually increased in quantity until it began to come independently of normal bowel action On examination by means of a speculum the whole of the rectum was found to be involved in ulceration, which extended upwards beyond reach of the proctoscope. The sigmoid flexure could be felt to be much thickened and was tender to pressure. Inguinal colotomy was performed the sigmoid being drawn out as far as possible in order to secure healthy bowel being opened the diseased part external to the abdominal wall was then cut away This was examined by the resident pathologist and proved to be tuberculous After the first week the lower bowel was regularly syringed out with the boric acid solution containing a tablespoonful of tincture of hamamelis to the pint, the stream being forced alternately from the anus to the colotomy opening and *vice versâ* Convalescence was very slow, but he steadily picked up strength and after going to the convalescent home was discharged much relieved

Remarks.—Apart from cancer stricture of the bowel usually results from ulceration with consecutive changes in the coats of the bowel but there is a specimen in the Leeds School Museum which shows a stricture due to gradual invasion of the bowel walls by tubercle spreading from glands in the mesentery and I have also seen and operated on, a case of stenosis produced by fibrous hyperplasia extending from a mesenteric tuberculous gland in process of cure In the first four cases here related there was no serious difficulty in coming to the conclusion that stricture was present and from the length of time that the obstructive symptoms constipation alternating with diarrhœa and pain, had existed that the narrowing was simple in character and not malignant. In three of the cases the family and personal history the early age, the loss of flesh and night perspirations were suggestive of the stricture being tuberculous, moreover there was an absence of history of typhoid fever or dysentery the two other chief causes of intestinal ulceration, and of hernia or injury which sometimes leads to intestinal stenosis. In Case 5 it was suspected that the tumour might be malignant and in fact, it was only on careful examination subsequently to removal that its true character was discovered. The cases related afford examples of tuberculous ulceration in parts of the intestinal tract from the duodenum to the anus, though the most common site of the disease is in the lower ileum and about the ileo-cæcal valve.

Chronic tuberculous ulceration leading to stricture is evidently not very common, though perhaps some cases put down as malignant, but where cure occurs after colotomy or enterectomy may be of this nature I have in my mind two cases of apparent cure of malignant stricture by colotomy, one in a man aged 33 years, in which I subsequently closed the colotomy opening after the health of the patient had become fully re-established and when there was manifestly no further need for the artificial anus and another in a man, aged 58 years, where the tumour exposed at the time of the colotomy has apparently disappeared and the patient is anxious to have the artificial anus closed.

Now although both of these cases had all the appearances and feel of carcinoma, I think the subsequent course of events makes it extremely probable that the intestinal thickening leading to stenosis was tuberculous, though proof is wanting The extension of the tuberculous process from the the appendix in Case 1 is apparently not a common condition, though seeing that the appendix is composed largely of lymphoid tissue it makes one wonder that it should comparatively rarely be attacked by tubercle, especially when the inflammatory attack is repeated over and over again. I have, however operated on at least five cases of tuberculous appendicitis, and the removal of the diseased part has issued in recovery and gain of health The following is a good example

CASE 7 *Tuberculous appendicitis appendicectomy*.—A youth, aged 17 years was sent to me on Oct. 1st, 1901 from the west coast, in such a weak condition that it was feared he could hardly bear any operation; he was suffering from night sweats and had a hectic temperature There was well marked tenderness over the cæcum with rigidity of the muscles. The history given was that he had had acute appendicitis 18 months before and that the abscess had been drained but the appendix had not been removed A recurrence of the attacks with deterioration of health led to two attempts at removal of the cause, but the appendix, it was said, could not be found At the operation on Oct. 6th there was well marked tuberculosis of the cæcum with miliary tubercles scattered in the neighbourhood, though the rest of the peritoneum was free. After carefully detaching numerous and firm adhesions, the appendix, which was tuberculous, was found in the centre of offensive thick caseous pus behind the cæcum and ascending colon. After removal of the appendix, clearing out and purifying the pus-containing cavity the abdomen was closed, a single gauze drain being used. Recovery was uninterrupted and he returned home at the end of the month A report was received from Mr C H. S. Vinter in December to say that the patient was well and getting out as usual.

The stricture in Case 1 was caused by a stenosis of the ileo-cæcal valve, but the lumen of the adjacent ileum and cæcum was also seriously narrowed by thickening of their coats. Cases 2 and 3 are characteristic examples of tuberculous ulcers which usually begin in the lymphoid follicles and adopt a transverse direction, following the course of the vessels around the whole circumference of the bowel, thus leading to stricture in chronic cases from the lymph which is thrown out to limit the ulcerative process, tending to contract. The situation in the ileum and the multiple characters of the strictures were also characteristic of tubercle. While in Cases 1 and 7 the adhesions to adjoining parts were most intimate in the other cases the affected part of the bowel was quite free, thus rendering operative measures quite easy and simple. In Cases 1, 2, 3, and 5 my decalcified bone bobbin was employed as a temporary splint over which to apply sutures, a method which I have described on numerous occasions and which I still employ and advocate as being simple and efficient. The physiological rest to the diseased parts secured by short-circuiting as in Case 3, and by colotomy as in Case 6, seemed to answer so well that where the radical operation of excision would involve serious difficulties or the patient is not in a condition to bear it I would not hesitate in future to be content with similar procedures and then to trust to general treatment and hygienic surroundings to assist in the cure If in the future my suggestion as to operative treatment in acute cases be thought advisable I anticipate that short-circuiting the diseased area will be found to be the more useful procedure as it is the easier and safer method to pursue but experience only can show whether these suggestions will prove of so much service in acute as they are in the chronic cases.

It is interesting to note that in Cases 1 and 7 where there were tuberculous nodules in the peritoneum—where, in fact, there was tuberculous peritonitis co-existent with the bowel disease—the mere exploratory operation had not cured or even arrested the tuberculous process, but that the radical operation of removing the principal focus of disease, or as in Case 3, the short-circuiting and so setting at rest the diseased bowel, was in all three cases effectual in putting a stop to the tuberculous peritonitis and so far as one can say without seeing the parts exposed in curing the more diffuse disease.

Now all surgeons must have had the experience of curing tuberculous peritonitis by simple abdominal section with or without drainage and probably many of us have also experienced disappointment in other cases where the effusion has returned after a longer or shorter interval. May the explanation of these recurrent cases lie in the fact that the original focus of disease in the ovaries, Fallopian tubes or bowel has not been removed and has been again the starting point for a further diffusion of the tubercle throughout the peritoneal cavity? If this be a correct surmise the remedy is quite clear that wherever the original disease may be it should be removed if that be possible without adding seriously to the risk of operation. I have acted on this principle in a number of operations for tuberculous peritonitis and have removed masses of tuberculous, mesenteric, or retro-peritoneal lymphatic glands tuberculous Fallopian tubes and ovaries loops of tuberculous intestine, and tuberculous appendices and this with such success as to encourage me in following up the method and in recommending it to the attention of other surgeons.

Leeds

PUBLIC HEALTH OF GLAMORGANSHIRE.—Dr W Williams, the medical officer of health of the county of Glamorgan in his annual report for 1901 which has just been issued states that during the year 22,173 births and 11,747 deaths were registered respectively, 604 deaths were attributed to pulmonary tuberculosis.

CLINICAL REMARKS ON SOME TUMOURS OF THE ANTERIOR ABDOMINAL WALL

BY FRED D BIRD, M S,
LECTURER ON SURGERY, MELBOURNE UNIVERSITY

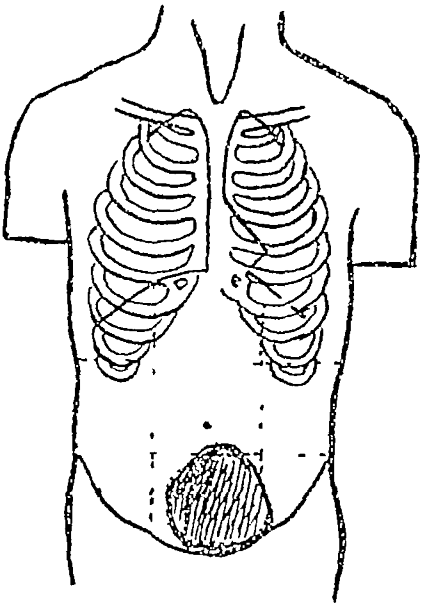
THOUGH numerous in variety tumours of the anterior abdominal wall are not common in practice. Their importance, however, is great and their diagnosis is often difficult. They frequently simulate sarcoma and a hopeless prognosis may be given or a mutilating operation performed under a mistaken diagnosis

It is not always easy to be certain that a tumour is in the abdominal wall—e g, the lax wall of a stout elderly woman lends itself to the palpation of abdominal tumours which may seem to the surgeon to be almost immediately beneath the skin Again the wall may be encroached upon from beneath so that it is implicated secondarily and the converse may obtain—a gumma may form in the rectus and a syphilomatous infiltration may spread inwards, binding together peritoneum omentum, and other structures in a large mass of which it is impossible to say that it is not sarcoma without incision and removal of a portion for microscopical examination. It is particularly of these specific cases that I wish to speak When we have satisfied ourselves as much as we can that the tumour is of the abdominal wall or is implicating the abdominal wall and is not an abscess our main anxiety is to be able to eliminate sarcoma from the diagnosis In the presence of a firm, solid tumour of the abdominal wall the surgeon has to choose between fibroma (which is said to be the commonest form of tumour here), sarcoma, carcinoma, and syphiloma. It is his manifest duty to be sure that it is not the last before he performs a large operation The exhibition of antisyphilitic medicines, often a trump card in diagnosis, may, and very likely will, give no help at all in these cases if the growth has attained even moderate size, in fact, by its absence of results drug treatment may turn us to the diagnosis of sarcoma with irremediable detriment to the abdominal wall of the patient. The greatest confusion exists as to the classification of hard tumours in this situation. They have been called "fibroma," "fibromyoma," "desmoid tumours," "fibrosarcoma," "fascial sarcoma," "sarcoma," and "carcinoma." One well known author speaks of them as "generally carcinomatous," another as "mostly sarcomatous," and a third as "fibromatous in the large majority of cases" Undoubtedly some of them are markedly malignant, but many of them, though of an infiltrating nature, have been removed and no recurrence has taken place. Injury often seems to stand to them in casual relationship These facts, with my own small experience of abdominal wall tumours, constrain me to think that many such tumours are syphilomatous in character and readily amenable to proper treatment. The short recital of a few cases will give in this connexion what has interested me very much In the first two cases the tumour was obviously in the substance of the abdominal wall.

CASE 1.—The history in this case was complicated by what seemed to be mild appendical attacks occurring on several occasions in a robust man of early middle age A tumour had formed over the appendical region in a few weeks and had reached the size of a closed fist when I saw the patient. It was very hard and it moved slightly Its edges were well defined and it was not painful to touch, though the patient had occasional pains in it on exertion He was certain that he had never had a chancre and a careful examination failed to show any symptoms of a possible syphilitic nature He had lost much weight and strength and looked worn, ill, and apprehensive Operation revealed the muscles on the way to the tumour hard and woodeny The tumour seemed to be fairly definite, it was cut into its depths and a slice was removed for examination Dr Mollison pathologist to the Melbourne Hospital, said that there were marked endarteritic changes to be seen and he believed it to be a gummatous mass beginning to soften at the centre With iodide of potash internally and mercurial innunction the tumour disappeared entirely and the patient resumed his usual health and strength It is only now after five years that I have discovered some signs suspicious of syphilis in his children but nothing further has occurred in his own person.

CASE 2.—The patient was a little boy, aged 20 months, who had been always healthy until a month before when there was a history of injury Since the injury he had wasted very rapidly and looked very ill and not far from death A very hard, not painful, only slightly tender, tumour was easily felt to the left of, and above, the umbilicus It was as big as a large mandarin orange, could not be moved, and was growing in the parietes Incision of the growth showed the futility of attempting to remove it and its fleshy section seemed to confirm the diagnosis of sarcoma. The case seemed very hopeless, but it was thought right to try specific treatment, although no conditions in either parent could be found pointing in this direction [The results were marvellous and the child was soon restored to health and his tumour rapidly vanished. Many months afterwards I attended the father for visceral syphilis from which he eventually died

CASE 3.—The patient was a strong man, aged 31 years, who had several attacks of what seemed to be mild appendicitis After one of these he noticed a lump in his lower abdomen to the right of the middle line This undoubtedly altered in size from time to time, it gradually increased and moved slowly over the middle line At first I thought that it must be a chronic infiltration of peritoneum round a diseased appendix, but its altering in position puzzled me very much The tumour seemed to be inside the peritoneum but implicating the substance of the wall as well. By this time the patient was losing flesh rapidly and also strength and I feared a malignant growth No history of syphilis was obtainable and no suspicious circumstances were to be discovered in his family Iodide of potassium and mercury were given, but although his health improved at this time (he went away for a holiday) the tumour steadily enlarged, and when he eventually submitted to operation it had attained a large size. Its proportions are shown in the accompanying diagram Its presence gave him great inconvenience when stooping and he had a good deal of trouble with micturition His health again failed and he was steadily losing ground The history of the growth now extended over nearly six months Felt from the front the tumour seemed to be in the abdominal wall, the skin did not move freely over it, giving an impression similar to that produced by a carcinomatous mass in the breast. Laterally the palpation was not at all suggestive of inflammatory infiltration, the tumour felt like a hydatid and dipped deeply into the pelvis but was not attached to bone. Rectal examination gave no information Incision into the growth conveyed the feeling of cutting inflammatory material to the fingers through the knife and the edges of the wound showed a general fibrosis of the connective tissue stroma. Muscle, fat and fascia could not be differentiated and an



Showing position and extent of tumour

irregularly shaped cavity was reached towards the centre of the mass. Great care was taken not to allow the exploring finger to press through into the peritoneal cavity A piece was removed which Dr Mollison said showed undoubted signs of syphilitic inflammation. The tumour now disappeared rapidly and the man is apparently as strong and well as ever He attributed the origin of the tumour to a strain in lifting Here the diagnosis was very difficult for a long time and was hardly less so even when the inflammatory infiltration of the skin had occurred. Here the tumour was too big and extended too deeply into the pelvis for any sort of removal of the whole mass, but another operative error could easily have been made—viz. making a large incision in order to explore the growth, thus damaging permanently the abdominal wall In this case appropriate medicine alone would not cause the disappearance of the tumour it required the stimulus of the knife as well as drugs to influence its absorption.

Case 4.—The patient was a man, aged 32 years, who during recovery from pneumonia discovered in his anterior abdominal wall below the umbilicus on the right side a steadily growing firm tumour with defined edges There was a history of injury with a doubtful history of syphilitic infection. The patient was sent to me to be operated upon for sarcoma. Incision into the tumour and proper medicine caused its rapid disappearance, although it was quite three inches long The microscopical appearance of a small slice removed was that of syphilitic inflammation Here the comparatively small size of the growth, its well marked definition from surrounding parts and the fact that it appeared to be confined to the parietes, invited an operation which would have been unnecessary and very damaging to the wall, for it is impossible to remove several inches of the rectus abdominis in a transverse manner without producing irremediable injury to the abdominal coverings. There was nothing in the examination of this case to suggest inflammation and everything to convince one of a new growth.

Case 5.—The patient in this case was sent to me for an opinion by my friend Dr G McCallum of Geelong My advice to him was to explore by operation, but I failed to divine the nature of the case The patient was an otherwise healthy man 56 years of age. He complained of a tumour in the stomach which he noticed eight months ago but it was only for the last six weeks, when he began to get pain after meals but no vomiting that it had caused him any trouble. He said that the tumour was steadily increasing in size. He had lost over two stones in weight On examination there was a swelling visible on inspection in the left hypochondrium and part of the epigastric region. The ribs protruded more on this side and a rounded edge was to be felt at the lower part of the swelling which was dense on palpation and could not be separated from the ribs. The percussion note over it varied at different times, probably owing to varying states of the stomach. Dr McCallum made an incision over the mass and on getting into the rectus muscle met with a very tough and gristly substance which bled rather freely He continued the incision so as to open the peritoneal cavity On this surface, corresponding to the mass to be felt from the outside was a soft fungiform excrescence. The stomach itself was practically free, only one small adhesion having formed The wound was closed after a small portion of the mass had been removed for examination which examination disclosed undoubted evidences of syphilitic infiltration.

My friend and colleague, Dr G R W Adam kindly allows me to relate a case occurring in his practice where he removed what he believed to be a fibroma growing in the anterior abdominal wall It was a hard well defined tumour discoid in shape, being flattened antero-posteriorly and about three inches across It was somewhat moveable and slightly painful to touch. The patient, a married woman, aged 40 years, had a serious illness—viz. pericarditis—some 10 months previously after which this tumour developed in the right iliac fossa. No specific history could be obtained. Dr Mollison pronounced the tumour to be a syphilitic gumma on its peritoneal aspect the omentum was adherent to some extent. In this particular case but little harm was done, as the tumour could be largely enucleated, but Koehler reports a case in which he removed what he thought was a large sarcoma extending from the left hypochondrium to the inguinal fold and from the linea alba to the axillary line part of the diaphragm was included in what was removed. The patient recovered it is true, but his abdominal wall was only skin all over the operated side, and the microscope proved the tumour to be not sarcoma but a huge syphilitic gumma.

This specific inflammation may be very circumscribed in its margins, so much so as to cause one to think that the mass must be a neoplasm, so marked is its definition In other cases the edge is infiltrated and the margin ill defined, blending gradually with the normal tissues, and in yet others clean-cut definition may obtain on the palpable edge of the mass and infiltration in other parts of its circumference. Clinically it is most interesting to note how the mass of newly formed material soon poisons the owner even as a really malignant tumour does. There was marked loss of strength weight, and health in these cases which lent colour to the diagnosis of malignant tumour Again, I believe if such a gummatous mass had attained any more than moderate proportions medicines alone would not remove it unless it had broken down or burst, by which time the patient would probably have been brought very low indeed. Incision is wanted to start the reparative process. I have not seen a gumma of the abdominal wall which has so far advanced in fibrosis as to resist both incision and medication, though I have met with them elsewhere.

Injury seems to play an important part in the inception of these masses as it does in other late specific manifestations and as it does in sarcoma, and this common factor increases the difficulty of diagnosis in what is really such a simple case as the following

Case 6.—A woman, aged 60 years of stout habit, while making a great muscular effort tore her right rectus below the umbilicus. Bleeding occurred into the rent at the time and also some time afterwards and a large tumour resulted, which could be moved with freedom laterally but not up from below where it passed down by a long thin pedicle to the pubes and behind it. When the case came under my care it was difficult to tell whether this long pedunculated flask shaped mass was in the abdominal cavity or in the wall and at the second bleeding which took place there was an abdominal seizure which fitted exactly that of the twisting of a pedicle. On the other hand, the tumour was somewhat flattened and felt like a fibroma or a hard sarcoma even when the examining finger was in the peritoneal cavity and a bimanual examination could be made. At one small spot only could anything like fluctuation be made out, but a second incision through the sheath of the rectus decided the diagnosis and allowed the removal of large masses of blood clot and some treacly blood from the part where the rectus had ruptured.

Abscess of the abdominal wall may sometimes simulate sarcoma very closely and hydatid cysts of which I know some five cases situated in the rectus, may easily deceive the surgeon. A careful examination of a patient with a hard tumour of the abdominal wall may throw much light on the case—e g the finding of metastatic nodules just under the skin in other parts of the body the presence of a cancer of the breast (especially an atrophic one) or of an operation scar showing that the breast has been removed or the recognition of specific lesions elsewhere, but when all our means of diagnosis, short of incision are exhausted it may still be impossible to decide between fibroma, carcinoma, sarcoma, and gumma. This makes it very advisable for us to stay our hand before we resort to a large operation for the removal of the mass and to content ourselves with a small incision into it to remove a portion for examination and to aid in its absorption should it be a gumma. If the case is sarcoma there are great mutilation and little chance of ultimate cure If it is a case of gumma a moderate incision into the growth and appropriate medical treatment are all that is necessary

Melbourne.

NOTES ON
THE RECENT CHOLERA OUTBREAK IN CANTON, SOUTH CHINA

By W J WEBB ANDERSON M B Ch.B. Vict
Fatshan Hospital, Wesleyan Mission Canton South China.

The presence of cholera (Asiatica) is no new thing in Canton. From time to time the outbreak assumes an epidemic form of grave dimensions and certain years like 1894 stand out in a peculiarly black lustre of their own

The shops in many of the Canton streets were closed, every inmate being dead Business was at a standstill and prices ran up enormously The incidence amongst the foreign community was not large This year, however, the scourge has carried off quite a number of Europeans from the small foreign section, whilst "several Tens die daily" amongst the native population Of this last statement—a translation of what the Chinese themselves say—there is ample evidence in the difficulty of securing coolie hire, in the difficulty in getting coffins, their large importation from the towns and villages round, and in the fact that three or four times the price has had to be paid to purchase an ordinary coffin as used by the natives Then the conditions which are so conducive to the spread of cholera have this year, as in 1894, been largely experienced Every year some small outbreak occurs towards the end of the dry winter season, February and early March. This year the country suffered from prolonged drought, so much so that the river water for 30 miles or more above Canton in certain streams was brackish, and in Canton itself the water from the wells, the main water-supply of the Chinese, was unfit for drinking At the same time the heat in Canton was intense for that time of the year, and the Chinese unclean untidy, and insanitary as are their ways, supplied other necessary conditions Extensive hospital practice amongst the natives and not a little amongst the foreigners has enabled me to compare the course of the disease and the effects of the treatment The onset in each case has been sudden This was particularly marked in the earlier cases when the disease was most virulent Diarrhœa and vomiting were early signs and in times varying from two to 12 hours the patient died In this stage of the epidemic delay in treatment meant certain death I have not seen one patient recover where treatment was delayed. I speak of the early weeks of the epidemic Later the epidemic seems to decrease in virulence. Spontaneous recoveries take place Generally speaking, the earlier the onset of cramps the worse the prognosis My own experience has gone to show that when cramps are a well marked condition the patient does not recover I have noticed that severe cramps in the limbs and the abdomen and large watery stools have gone together Amongst my European patients, as my Chinese, little cramp and only small evacuations of watery fluid have been followed by recovery under treatment. My first and my last European cases afford illustration

CASE 1.—The patient was a German merchant, aged 45 years He was not a teetotaler but was temperate. He was not overworked. He was subject to diarrhœa and "biliousness" He dined on the steamer coming up to Canton He said that he had eaten ' shrimp curry and salad " After dinner as he sat on deck chatting he felt a little fulness, so he took about 20 grains of bicarbonate of soda in water from his cabin He retired to rest about midnight and was restless There was a tendency to diarrhœa about 3 A M Between 3 and 6 A.M he had several attacks. He got home by 8 A M feeling "seedy" and he went to lie down At 9 A.M cramps came on in the legs which continued until 10 30 A M when I saw him. His condition then was one of intense collapse Cyanosis was general and he had frightful cramps He was pulseless at the wrist and the temporal pulse was slight. The vomiting had ceased Two large evacuations of typical rice watery stools occurred Restlessness was present. He was speechless or could speak only with difficulty He gradually sank into a quiet collapsed condition, in which he shortly died. The heart reacted only slightly to hypodermic injections of digitalin, strychnine, caffeine, and brandy Had he been seen at 6 A.M instead of four and a half hours later he might have been saved Just after this case I saw a Chinese woman presenting very similar condition, but delay in being called also was followed by death, neither hypodermic medication nor intravenous injection of salines being followed by any rallying effect

CASE 2.—A colleague and his Chinese boy were taken ill together and both came to hospital The boy elected to go home and was dead by 6 A.M next morning—i.e , in 12 hours. My colleague was treated at once On admission he was found to be suffering from diarrhœa which was fæcal in character , vomiting and moderate collapse were present. The stools rapidly became typical and his appearance altered. The eyes and cheeks became shrunken, the amount of shrinkage being astonishing The pulse was 110 , slight fever only was present. The treatment consisted of rest in bed and hot-water bottles and subcarbonate of bismuth and lime water to try to stop the vomiting , this was of little effect, however The stools were small, being from two to three ounces at a time only, but evidently of an irritating character A high enema of warm water and Condy's fluid, pink solution, was given, followed at once by 30 minims of tincture of opium, with 15 minims of solution of atropine (1 in 100) The vomiting ceased in a few minutes nor did it return as long as opium was administered per rectum. Stools occurred from every 10 to 15 minutes The enema was repeated and 10 grains of salol were given every hour by the mouth, with 30 grains of bismuth subnitrate in one dose three times a day Occasional doses of a pill of acetate of lead with one-twelfth of a grain of opium were given on the second and third day and the salol was reduced to four times a day (10 grains to the dose) On the second day the pulse was 98 and the stools were a little less frequent and still smelt. The cramp was not marked On the third day the pulse was 94 The stools occurred about every one and a half hours , they were still small After this improvement was steady The patient took meat juice after the second day at frequent intervals He sat up for an hour or so on the eighth day The first formed stool occurred about the tenth day There was no relapse. He finally went on a sea voyage in order to gain strength The patient was not given alcohol in any form save on two occasions when from pain of cramp at the anus he fainted. In this case the advantage of immediate treatment is obvious, otherwise the patient must have shared the fate of his servant. I think that the pushing of salol (watching the urine at the same time) was a strong factor in his recovery, together with the high enemata

Canton

SOME CASES OF CHRONIC PANCREATITIS

By B G A. MOYNIHAN, M.S Lond , F R.C S Eng ,
ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY CONSULTING SURGEON TO THE SKIPTON HOSPITAL AND TO THE MIRFIELD MEMORIAL HOSPITAL

It is only within recent years that the importance and the frequency of chronic inflammation of the pancreas have come to be recognised. Until Riedel first called attention to the association of thickening of the head of the pancreas with cholelithiasis, chronic inflammation of the gland was not recognised as a clinical condition , and for several years the association was considered most infrequent and of no great surgical importance. In 1900 Mayo Robson, in a lecture published in THE LANCET of July 28th, p 235, and subsequently in a paper read at the International Medical Congress in Paris emphasised the surgical importance of chronic pancreatitis, and repeated the statement of Riedel as to the frequency of its dependence upon gall stone irritation

Chronic pancreatitis as seen by the surgeon is always secondary It is dependent upon infection extending from the intestinal canal or from the bile passages, upon the long standing irritation of gall or pancreatic stones, or upon the invasion of malignant disease which may be primary in the gland itself or may extend into the gland from the duodenum or stomach Certain toxic substances brought by the blood to the gland may set up chronic inflammation , of such are the poison of syphilis, the organism of tubercle, and, it is confidently said, alcohol Pre eminent among all these causes we must without question place cholelithiasis Associated with, and dependent upon gall stone disease may be found every grade in the extension of inflammation to the gland In the slightest cases a little thickening of the head of the gland is found , that portion nearest to the duodenum is denser and stiffer than the body or tail In the severer cases the whole head and a part of the body also may be enlarged and extremely hard and solid, feeling like a plaster cast of an enlarged gland But in all cases the duodenal end is more profoundly affected by the changes which have taken place than is the body The tail is implicated only in the long standing and severer instances During the last two years, since my attention was more especially directed to the pancreas in operations in the upper part of the abdomen, I have seen several cases of chronic pancreatitis. These cases illustrate the association of the inflammation of the gland with pancreatic calculus, syphilis, stone in the ampulla of Vater, stone in the common duct, and suppurative cholangitis due to stone in the gall bladder and cystic duct. The following is a brief summary of my cases. The case of pancreatic calculus, the first recorded in which a correct diagnosis was made and successfully acted upon, is related at length in THE LANCET of August 9th, 1902, p. 355, and the following is a brief epitome of it.

CASE 1.—A married woman, aged 57 years, was seen with Dr. H. M. Robertson of Roundhay. The symptoms which I had to discuss, the relative value and significance of which I had to determine, were briefly these: steady loss of health, gradual wasting, irregular pigmentation of the skin in patches of the colour of *café au lait* (very closely resembling the pigmentation of molluscum fibrosum), persisting attacks of epigastric pain and uneasiness of the type of hepatic colic, though less severe and unattended until very late in the history by jaundice, which was then always trivial though unmistakeable, and pain passing through from the front of the abdomen to the middle of the back. There was no rigor or any complaint of sensations of heat or cold. The stools were occasionally "frothy" and "greasy." On examination under chloroform some indefinite swelling could be felt above the umbilicus and a little to both sides of the median line, though chiefly to the right. I considered that the evidence warranted a diagnosis of chronic pancreatitis. To explain the onset of this condition I suggested that a pancreatic calculus was present, that its transit down the canal of Wirsung had been attended by the attacks of epigastric colic, and that as it approached the ampulla an inflammatory condition had been started in the common duct and a slight jaundice had thereby resulted. Upon this diagnosis I felt justified in basing my suggestion for operative treatment. If chronic pancreatitis were found and no cause were discoverable the condition could be relieved by drainage of the gall bladder; if a pancreatic calculus were found it could be removed either from the pancreatic duct or from the ampulla of Vater if it had travelled so far.

Operation was performed on May 22nd, 1902. The abdomen was opened two inches to the right of the median line by an incision about seven inches in length and the fibres of the rectus were split. On opening the abdomen the gall bladder at once presented; it was tense, well filled, and free from any adhesion; the cystic duct, hepatic ducts, and common ducts were all thoroughly examined, the liver being rotated for that purpose. The ducts were all free from adhesion and nothing abnormal was felt. The head of the pancreas was very much enlarged and hard, the body less so, but still larger and denser than the normal. The chronic pancreatitis affected the whole gland but chiefly the head and in least degree the tail. The duodenum and the head of the pancreas were carefully examined and a small lump was then felt, as it seemed, between the two. The swelling did not feel like a stone and I expressed a suspicion that it might prove to be a growth deep in the ampulla of Vater. I therefore opened the duodenum and exposed the papilla Vateri; this was quite normal in appearance. The lump, however, was felt to be only a short distance beneath the mucous membrane. The papilla was therefore laid open and the cut edges were seized with a small French vulsellum and held apart. At the bottom of the ampulla a small object could be seen and the knife touching it could be felt to be impinging upon soft stone. A small scoop was therefore passed into the ampulla, pressure was made upon the head of the pancreas close to the duodenum, and the stone was lifted out. So far as I could judge—and the ampulla was well opened—the stone lay in the termination of the pancreatic duct with its end projecting into the ampulla. It was certainly not wholly in the ampulla, for it was not at once exposed on slitting up the papilla; equally certain it was not in the end of the common duct. The duodenum was stitched up with continuous sutures. The gall bladder was aspirated and drained and the wound was closed in the usual way. The tube was removed on the seventh day and the wound then slowly healed. The condition of the liver was normal. There were no adhesions around it or any trace of pigmentation.

The following is the report of Dr. J. A. Milroy on the stone removed, clearly showing its pancreatic origin: "The stone contains nearly 50 per cent. of calcium carbonate. A small portion of the solution in which the magnesium was estimated was unfortunately used for qualitative testing, so that I cannot state the exact quantity of magnesium present. These were the only inorganic substances found. I was somewhat surprised to find phosphates absent. The organic substances consisted almost entirely of proteid. Traces of organic substance soluble in alcohol and ether were present. In the residue from the alcoholic and ethereal solutions cholesterin and fat were the only bodies identified. Purin bases and uric acid were absent. The quantity of the original powder was rather too small to allow of an accurate estimation of the constituents."

When seen in September, 1902, this patient had steadily gained in health since the operation and was better and heavier in weight than she had been for years.

CASE 2. *Syphilitic pancreatitis: gumma in the head of the pancreas.*—The patient was a woman, aged 51 years, who was seen with Mr. J. F. Woodyatt of Halifax. For 10 years she had symptoms which were referred to pyloric obstruction and which consisted of pain, which was intensified by taking food in moderate or large quantity, occasional vomiting, and constantly recurring attacks of "spasms." During the last year or more in several attacks the pain had been most intense over the gall bladder region, jaundice had followed, and gall-stones had been found in the motions. The pain had constantly been more severe during the last few months and a gradual loss of flesh had been observed. On examination there was a general tenderness in the upper part of the abdomen to the right of the middle line. No tumour or undue resistance was observed.

Operation was performed on Oct. 1st, 1901. The abdomen was opened by the usual vertical incision over the gall bladder region and the fibres of the rectus muscle were split. On exposing the gall bladder and bile-ducts a number of adhesions were found. These were separated and a good view of the whole region was obtained. No stones were present in any part of the bile-passages. The head of the pancreas was noticed to be very much enlarged, a distinct rounded and very dense mass equal in size to a billiard ball being felt. There was no enlargement of the body or tail. A doubt was felt as to the nature of this local swelling, the diagnosis resting, as it seemed, between malignant disease and chronic pancreatitis, but an opinion in favour of the latter based upon the clinical history was expressed. The gall bladder was aspirated and drained and the parietal wound was closed. There was some trouble from an acute attack of bronchitis for a week or more after the operation, but the patient otherwise progressed well and the wound healed soundly after the tube was removed on the eleventh day from the gall bladder.

At the end of November Mr. Woodyatt asked me to see the patient with him again as he had noticed masses in the abdominal wall as to the nature of which he was in doubt. I saw her on Dec. 1st and found her condition to be as follows. The wound was soundly healed. About two inches to the left of its lower end was a hard smooth ovoid lump of about the size of a pigeon's egg. At the lower part of the abdomen, just above the right external abdominal ring, was a similar lump of about the size of a hen's egg in the abdominal wall. There were three other lumps of the same kind though smaller in the abdominal wall and two on the chest wall. At first I thought that these little nodules must be secondary growths, the mass in the head of the pancreas being the primary source, but on reflection it seemed more likely that they were gummata and that the distinct localised enlargement of the head of the gland was also gummatous. I therefore suggested a trial of iodide of potassium, with the result that all the nodules speedily vanished and the patient regained, and has since retained, perfect health. In July, 1902, Mr. Woodyatt writes that "Mrs. —— is still getting on well and is taking food better than she has done for years."

Remarks.—Syphilitic disease of the pancreas may assume two forms, a chronic diffuse interstitial inflammation or a localised gummatous inflammation. There can be no doubt, I think, that in this case a gumma had formed in the head of the gland, the incidence of the gumma being determined, as is often the case, by the traumatism inflicted by the constant passing of gall stones. Syphilitic pancreatitis has recently been studied by Schlesinger.[1] It is more common in children than in adults and is frequently a congenital lesion. The disease begins as a periarteritis. Oppe has recently described a case in an infant who lived but three hours. The gummatous form is extremely rare. Cases are recorded by Drozda, Chvostek, and Battle. In a case related by Drozda the pancreas was represented by a mass of fibrous tissue containing breaking-down gummata.

---

[1] Virchow's Archiv, 1898, p. 501.

Glandular elements were only seen in the head There was characteristic evidence of syphilitic cirrhosis in the liver also

CASE 3 *Calculus in the ampulla of Vater, chronic pancreatitis, duodeno choledochotomy* —The patient, a female, aged 41 years, was admitted on March 23rd, 1901. The history was that attacks of pain in the right hypochondriac region had been intermittently present for eight or nine years 16 months before admission jaundice was noticed for the first time Similar attacks of pain followed by jaundice had been noticed several times since that date On admission she was jaundiced and the colour had been present, though varying in tinge, for four months A stone in the common duct was diagnosed The abdomen was opened and a stone was found impacted in the ampulla of Vater The head of the pancreas was densely hard—as hard as stone. I remarked at the time that the gland felt more like a plaster cast of a large pancreas than like a normal organ. The duodenum was incised and the stone was removed The gall bladder was drained for 11 days The patient made a good recovery and is now quite well.

CASE 4 *Stone in the common duct, choledochotomy* —The patient, a married woman, aged 58 years, was seen in April, 1901 The first attack of biliary colic occurred at Christmas 1896 This had been followed by others at almost regular intervals of three months until January, 1901 when the severest attack of all took place. She was confined to bed after it for three months and it was after this that she suffered from continuing, though varying, jaundice. Shivering was noticed on several occasions, on each the pain was rather worse and the jaundice was a little deeper

At the operation a host of adhesions were found around the common duct, gall bladder, and duodenum A stone was found tightly fixed in the common duct near the termination of the cystic duct An incision was made on to it and a stone equal in size to a Barcelona nut was evacuated. A couple of drachms of pus followed the stone The common and hepatic ducts were thoroughly explored and found to be clear The head of the pancreas was much enlarged and extremely hard, feeling as solid as stone. The adhesions which surrounded it were unusually tough and strong and were with difficulty separated Before the separation was effected the enlarged head of the gland felt very like a malignant growth A large drainage-tube was fixed by one stitch into the common duct and the abdominal wound was closed round the tube After the operation there was retention of urine cystitis following upon catheterisation Healing of the wound was delayed by cellulitis due probably to infection from the pus escaping from the cystic duct. Bile was discharged freely from the wound for several weeks A year later the patient was quite well and her medical attendant informed me that "the relief from operation has been complete."

CASE 5 *Stone in the common duct, marked interstitial pancreatitis, choledochotomy* —The patient, a single woman, aged 55 years, was sent to me by Dr H J Clarke of Doncaster She stated that two and a half years ago she had the first attack of jaundice, preceded by an extremely severe attack of pain lasting for two days The jaundice passed away in 14 days, and afterwards she felt quite well In December, 1901, a similar attack of pain over the liver, passing through to the right scapula, was followed by jaundice slight in character and lasting only for five days After recovery from this attack she felt weak, easily prostrated, and had a "loathing for food." Flatulence was distressing and her weight gradually decreased Six weeks before admission she had a similar attack of pain, followed by jaundice, since then the jaundice had varied in depth of tinge, but had never disappeared, the pain had varied, but a dull aching sense of oppression and weight had always been present. She had had several shivering attacks during the last six weeks She had lost one and a half stones in the last three months The jaundice was said by her friends to be less in the morning and to get gradually deeper in tinge during the day On examination there were tenderness and rigidity in the gall-bladder area but nothing definite could be felt

Operation.—A long incision was made. The gall bladder was found buried in adhesions, thick and contracted There were many adhesions between the abdominal wall, the liver, duodenum, transverse colon, and bile ducts, which were so firm and so widespread that rotation of the liver was not possible. A stone was tightly wedged in the common duct. As the common duct could not be brought to the surface it was necessary to cut down upon the stone in the duct and to remove it with a scoop The stone was of the size of a nutmeg The hepatic and the rest of the common duct were explored, but no other stone was discovered. A large tube was fixed into the opening made into the duct and the abdominal wound was closed. The tube came away on the eleventh day The wound rapidly healed and the patient is now quite well and free from any pain, discomfort, or jaundice The head and body of the pancreas were densely hard and slightly enlarged The condition which I found was certainly the most exemplary instance of chronic pancreatitis that I have observed Mr P J Cammidge, after examining the urine, said that it reacted better to his test for pancreatitis than any sample of urine he had previously examined The following is his report "High colour amorphous urates, no albumin, no sugar A well marked reaction for chronic pancreatitis was given Some obstruction to the common bile duct or pancreatic duct is probably present with a considerable degree of consequent chronic pancreatitis"

CASE 6 *Stone in the common duct, suppurative cholangitis, chronic pancreatitis* —The patient was a female, aged 70 years. For the last eight years the patient had suffered from recurring attacks of pain which were localised in the right hypochondriac and epigastric regions The attacks came on spontaneously, caused faintness, coldness, and vomiting, and lasted as a rule for about four hours The pain had gradually increased in severity during the last year and had been nearer the middle line In recent attacks she had often been cold and had shivered and subsequently had sweated profusely, she had had, in fact, miniature rigors of slighter intensity than those usually seen Up to eight weeks previously she had never been jaundiced. After an unusually severe attack at that date jaundice was noticed which quickly deepened and then almost faded away, to return as deeply as ever She had lost about two stones during the last seven months

Operation was performed on August 27th, 1901. The usual sickle-shaped incision was made and the gall bladder region was exposed The omentum was found intensely adherent in all directions to the gall bladder area. These adhesions were stripped except at the fundus of the gall bladder where they were so dense that the gall-bladder was cut across with scissors and the fundus was left adherent to the omentum On dissecting the fundus out it was found that a stone had ulcerated through the gall bladder into the omental adhesions which had protected the general peritoneal cavity The fundus was removed piecemeal and bleeding vessels in the omentum were secured. The liver was now rotated so as to put the ducts on the stretch and to expose their whole length. A stone was felt in the common duct about three quarters of an inch below the junction of the cystic duct. The common duct was incised, the stone was removed, and the duct, after exploration had revealed its patency and the absence of other calculi was stitched up with a continuous suture of catgut. The pancreas was closely examined. The head was found enlarged and very hard, the body and tail felt normal The difference in the consistence of the duodenal end and the tail was very striking A tube was placed in the gall bladder and the abdominal incision was then closed

Mr Cammidge reported as follows upon the urine "The specimen quickly gave a well marked reaction such as I am accustomed to find in cases of pancreatic disease I therefore conclude that there is extensive inflammatory change in the pancreas and I should expect from the appearances seen that this is most likely due to malignant disease, although I am not quite certain on this point."

CASE 7 *Multiple calculi in the gall bladder, acute cholangitis, chronic pancreatitis* —A married woman, aged 60 years, was seen with Dr L B Hayne of Harrogate The history was that the patient had suffered for many years from "spasms," the pain being chiefly in the right upper quadrant of the abdomen, but radiating thence to the whole body She had never been jaundiced On July 18th, 1902, she had a "feverish attack" Her temperature was 101° F and she had, general muscular pains and frontal headache On the 20th she had an intense colicky pain in the upper part of the abdomen with tenderness in the epigastrium, accompanied by retching and slight vomiting The pain continued paroxysmally ti the 24th In the early morning of the 26th there w another attack, the pain starting from the epigastric notch and radiating thence around the lower edge of the thorax o both sides. The colon was distended There was no sickness. The abdomen moved freely on respiration. There was tenderness under the right costal margin, especially at a point about two inches above and externally to, the umbilicus, under which a distinct resistance to pressure was felt. Later in the evening she was cold and very collapsed. On the 27th the conjunctivæ were tinged with yellow and bile was present in the urine. On the 27th the stools were clearly coloured and 11 small calculi were found in the motions, some were bright green in colour others were lighter but all were cheesy in consistence. On the 30th there was another attack and on the following day three calculi were found in the stools. The next attack was on August 13th and from this date they have been repeated every 48 hours, but no calculi have been found. The attacks usually commenced with a feeling of weight in the epigastrium flatulence was then complained of, and the pain commencing in the upper part of the abdomen, spread generally and became extremely severe, causing collapse and coldness of the limbs. The pulse-rate had varied from 48 to 72

On August 25th the operation was performed The usual incision, splitting the rectus near its outer margin, was made and the gall bladder area was exposed. There were many adhesions those about the ducts and the head of the pancreas being extremely dense and with difficulty separated The gall bladder and the adjacent portions of the liver were thinly adherent to the abdominal wall, omentum and stomach. The head of the pancreas, which was buried in adhesions, was slightly enlarged and very hard, almost stony in consistence. The gall bladder was opened and cleared of 81 stones The cystic and common ducts were free. The gall bladder was drained and the wound was closed in the usual manner The patient made a very good recovery

Mr. Cammidge examined the urine passed on the morning of the operation and wrote 'It gives a slight reaction but I should not like to offer more than a guarded opinion on such a feeble result.

Varieties of chronic pancreatitis —Opie distinguishes two forms of interstitial inflammation of the gland—*interlobular* in which the inflammatory process is localised chiefly at the periphery of the lobule and *interacinar* in which the process is diffuse, invading the lobules and separating individual acini and involving the islands of Langerhans. In all the preceding cases the type of inflammation was the former—the interlobular The distinction between the two forms is important, for in the interlobular variety the islands of Langerhans are rarely affected and then only in the latest stage, and therefore diabetes is exceptional. In 11 cases related by Opie in one only was diabetes of a mild type observed in this the sclerosis was far advanced and affected the islands of Langerhans. In two out of three cases of interacinar pancreatitis diabetes was present.

The relationship of the islands of Langerhans to diabetes has recently received considerable attention from pathologists. Szobalow in 1900 reported two cases of diabetes in which the islands could not be discovered. Opie was the first to make a systematic study of the subject and his results are embodied in most valuable papers in the *Journal of Experimental Medicine*[2] Weichselbaum and Stangl[3] examined the pancreas in 18 cases of diabetes and found it affected in 17 Herzog reports four cases of diabetes in which changes were found in the islands. Steele[4] has summarised the results obtained by previous investigators. Three distinct types of lesion have been described in these cases. 1. An atrophy of the pancreas affecting the secretory glandular epithelium but much more intensely the islands of Langerhans These bodies show evidence of cellular degeneration and are diminished in number There is an increase in the interlobular and interacinar connective tissue which Weichselbaum and Stangl hold to be secondary to the atrophy of the epithelium. 2. Hyaline degeneration of the islands of Langerhans as described by Opie. 3. A chronic interlobular and interacinar interstitial pancreatitis in which the islands have been involved apparently rather late in the process. In this variety the islands appear to resist the invasion quite vigorously and the secretory glandular epithelium is in a much more advanced stage of degeneration than the cells of the islands. The occurrence of glycosuria in this type is usually less pronounced

The cases that I have related show very clearly the various stages in a progressive inflammation of the gland. In the earlier stages a thickening of the duodenal end is found and is merely incidental, being merged in a more serious condition, giving rise to no special symptoms and requiring no special treatment other than the removal of the cause upon which it depends. In a more advanced stage the pancreatic inflammation becomes the dominant condition and in the later stages it may exist alone, long after the irritation which gave rise to it has subsided.

Treatment.—The treatment of chronic interstitial pancreatitis must be mainly concerned with the removal of the cause of the gland implication. But in all cases drainage of the gall bladder is necessary It is my custom to fix an India rubber tube into the gall bladder or into the common duct by a single catgut stitch and to allow the tube to remain until released by the absorption of the suture. This generally occurs between the tenth and twelfth days and the wound then speedily closes

Leeds

PYTHOGENIC PNEUMONIA.

By A. H. Copeman, M D Dub. M R.C.S Eng
L.R.C P Lond

The following details of a succession of cases of pneumonia in one household may not be without interest.

About nine months ago a man, with his wife and family of five children took possession of some old business premises The house was fairly commodious and in good condition but several previous occupants had complained of illness during their tenancy and one of them had died some years before from typhoid fever The drains were said to have been subsequently overhauled and some slight derangements of the system rectified. Almost from the beginning of their occupancy the new tenants commenced to have illness amongst the household. Feverish" and bilious attacks were common amongst the children and one boy in particular suffered continuously from a most distressing cough for which no cause could be assigned and which only yielded to large doses of aperient medicines. The head of the family himself found his energies unaccountably flagging and he gradually assumed the worn out and fagged appearance of the convalescent from acute disease his wife indeed, being the only occupant of the house who retained anything approaching to her former state of health.

One evening I received an urgent summons to attend the eldest son. He had been that morning in about his usual state of health and his mother imagined that he was in for one of his usual attacks of coughing but she was rather anxious as he appeared to be so much more generally ill than was usually the case. I found him flushed and breathing heavily his respirations being 50 his pulse 120 and his temperature 104° F I prescribed the usual dose of calomel and an ordinary fever mixture In the morning I found distinct signs of commencing consolidation at the left base the tongue was already dry and brown and the child was evidently acutely ill On the third day of his illness I was informed that two of the other children appeared to be unwell. One, a girl about seven years of age, did not present the appearance of being acutely ill and in fact, beyond having a temperature of 101° for a couple of days she did not give me cause for any anxiety but the other child an infant, nine months old subsequently went through a very severe attack of broncho-pneumonia, barely escaping with his life. On the next morning I found the mother herself in bed she had been taken with severe pain in the left side during the night having been perfectly well on retiring to rest, and she also subsequently went through an acute attack of pneumonia, ending in crisis on the sixth day The father had gone away for a change of air only the day previous to that on which his eldest boy was seized and in response to telegrams he arrived back the very day that his wife was taken ill. That evening when I paid my usual visit I found him crouching over the fire complaining of severe headache and of feeling altogether very ill. I ordered him to bed at once and the next day I found him to have well marked signs of lobar pneumonia of the left base He very rapidly became worse and on the morning of the fourth day of his illness owing to his extremely critical condition, inhalations of oxygen and hypodermic injections of nitrate of strychnine were resorted to The effect was most encouraging and for two days I had some hope of his ultimate recovery A jaundice which had developed on the third day now, however, added to our anxieties There was intense tenderness and swelling over the region of the liver, and the urine, which had become very scanty, had the appearance of consisting almost entirely of bile. On the sixth day he became absolutely unconscious, inhalations of oxygen and the exhibition of strychnine no longer brought any benefit, mucus began to collect in the tubes, and at night he died, decomposition beginning to set in almost immediately after death

[2] Vol v Nos. 4 and 6.
[3] Wiener Klinische Wochenschrift October 1901
[4] American Journal of the Medical Sciences July 1902.

The chief features of the epidemic were (1) the very sudden onset, (2) the high temperature, and (3) the extraordinary manner in which the patients appeared to be prostrated from the very onset of the attacks

Immediately after the seizure of the third child I instructed the town surveyor to apply the smoke test to the drains and his report is appended. On receiving it I at once made arrangements for the patients to be removed to another house, but the very serious aspect which the father's illness had assumed rendered this inadvisable, if not impossible I might add that on taking possession of the premises a room situated below the level of the street, which had been previously used as a box-room, was converted into the dining and general living room of the family and it was this room which became absolutely filled with the smoke on the application of the test in the usual manner from outside the house

Report of the surveyor to the urban district council "I applied the smoke test to the drains at the above premises with the following result In applying the test to the gulley in the covered yard a direct communication was found to exist between the drain and the interior of the premises, the smoke finding its way from under the floors into the cupboard around staircase. I also found an untrapped opening in covered yard (leading direct to drain) and a bell trap in the front area."

ON TWO CASES OF PARALYSIS COMPLICATING GONORRHŒA[1]

BY T R. GLYNN, M D, F R.C P LOND,

PROFESSOR OF MEDICINE, UNIVERSITY COLLEGE LIVERPOOL CONSULTING PHYSICIAN TO THE ROYAL INFIRMARY, LIVERPOOL.

SOME of the complications of gonorrhœa have long been recognised, for they are manifestly due to an extension of the urethral inflammation or to accidental inoculation I allude to stricture, abscess in the neighbourhood of the urethra, cystitis, pyelitis, orchitis, and ophthalmia. Other accidents of the disease have been more recently distinguished—namely, the various consequences of ascending infection in the female—ovaritis, salpingitis, and peritonitis The affections due to a general infection are not so obviously related to the urethritis Among these may be enumerated arthritis in various forms (I may say in passing that the agency of urethritis in the development of one variety of articular disorder, a chronic but progressive osteo arthritis, is particularly likely to be overlooked owing to its insidious evolution), endocarditis (a most serious accident, and one that, as recent experience has taught me, may prove fatal in a few weeks), phlebitis, pleurisy, and disorders of the nervous system, with which latter complications we are just now particularly concerned

The discovery of the gonococcus and the determination of the pathogenic qualities of the organism contributed much to our knowledge of the processes of local and general infection Although the gonococcus has sometimes been detected in the blood and in the inflamed tissues when general infection with local manifestations has followed a urethritis, it is probable that in many cases these secondary troubles are excited by the toxins of the organisms rather than by the organisms themselves, moreover, among the agents capable of giving rise to infective troubles are the ordinary pyogenic cocci, often associated with the specific microbe of gonorrhœa.

Gonorrhœa is happily rarely attended with complications involving the nervous system, and accidents of this nature occurring as they may during the progress of what is sometimes regarded as a trivial affection are worthy of attention. Although I am never called upon to treat gonorrhœa I have met with two cases of this disease in hospital practice in which the nervous system was involved I believe these cases to be of sufficient importance to justify my directing attention to them and offering a few clinical remarks suggested by them, and I trust that the subject may be sufficiently interesting to warrant the selection

In seeking for any notice of the nervous accidents of gonorrhœa it is not necessary to go further back than the year 1863 when Stanley described certain paraplegic affections which he had met with in gonorrhœa associated with bladder or kidney trouble According to the views expressed by him the disease of the urinary organs produced a morbid impression on the cord through sentient nerves which by reflection downwards occasioned impairment of sensation and motion, or what he termed urinary paraplegia. Gull, in his lectures on Paraplegia,[2] relates three cases of loss of power of the lower extremities accompanying gonorrhœa and considers that the paralysis was due to an inflammation of the cord occurring as one of the proper sequelæ of the urethritis and produced in the same way as the arthritis Ricord, the weight of whose observations on such a subject cannot be over estimated, states that he has seen symptoms of cerebral and spinal compression arise during the progress of a gonorrhœal arthritis and that the symptoms of paralysis seemed to vary with the extent of effusion in the joints as if it depended on the same mechanism Charcot, who discusses the pathology of Gull's and similar cases, looks on them as examples of myelitis excited by an ascending neuritis originating in the nerves of the inflamed bladder or kidneys[3] He also in 1887[4] relates a case of chronic gonorrhœal arthritis and bursitis with spinal symptoms of a different character—namely, weakness of the legs, muscular atrophy, and spastic disturbance, the arthritis was most marked in the hips, knees, ankles, metatarsal and phalangeal joints, and there was inflammation of the bursæ of the soles of the feet. He also refers to two cases by Hyem and Parmentier presenting precisely the same symptoms Charcot remarks that while he believes that a myelitis may be set up by extension of inflammation to the cord through neuritis associated with gonorrhœal pyelitis, he considers that such an accident was not accountable for the spinal symptoms in these cases He does not believe that the nervous disturbance was due to a specific infection in any degree resembling that of the joints, but that it arose from a reaction on the trophic centres of the cord, of excitations to which the nerves in relation with the diseased joints were subjected, the irritative impulses were reflected through the posterior roots and multipolar cells of the anterior cornua, and gave rise to dynamical trouble, and subsequently perhaps might produce organic mischief The symptoms referred to—disturbance of sensibility, exaggerated reflexes, diminished muscular power and muscular atrophy—may be met with in any forms of chronic arthritis and have been especially studied by Vulpian, Charcot, and Raymond This theory appears to me to be only a more elaborate form of the older theory of urinary paraplegia, with a wider application Vulpian[5] and Raymond also narrate cases of gonorrhœal arthritis with these peculiar spinal troubles and accept Charcot's views Hyem and Parmentier, on the other hand, in their "Contributions to the Study of the Complications of Gonorrhœa,"[6] adopt a different explanation, maintaining that the muscular atrophy and the other nervous disturbances of the lower extremities in their patients originated in a specific gonorrhœal infection causing a meningo-myelitis

It is evident that much difference of opinion has prevailed as to the nature of the nervous accidents which I have referred to The trouble in the spinal cord was by the majority of physicians regarded as not dependent directly on a gonorrhœal infection of that organ, but later, when the pathology of gonorrhœa was better understood, the view enunciated by Gull, that the urethritis "probably brought on paraplegia through a purulent affection of the blood, or through some more specific taint, was generally adopted. Leyden in 1892 remarks that it is impossible to doubt but that certain forms of myelitis are due to gonorrhœa and to the gonococcus itself or to its toxins. Fürbringer[7] has published a case of cerebro-spinal meningitis with gonorrhœa. Fluid obtained by lumbar puncture contained the gonococcus and the post-mortem examination demonstrated the existence of the gonococci in the exudation of the inflamed membranes. So that while we recognise that *gonorrhœa* may excite reflex trouble such as Charcot describes and also a myelitis through an ascending neuritis we also believe that it may by its specific organisms or their toxins or by a mixed infection give rise to inflammation of the cord or its membranes

With the recognition that a peripheral neuritis might cause a paraplegia or a more diffused paralysis came the knowledge that such conditions were not necessarily due to a functional or an organic lesion of the cord and when further it became manifest that the peripheral nerves were especially prone to inflame under the action of many and diverse toxic agents and that these toxic agents might be developed within the body as well as be introduced into it from without, our insight into the pathology of *paralytic* affections occurring in association with infective disorders became much more profound.

The infections, then, are active agents in the production of neuritis and cerebro-spinal troubles and in the infections by the pyogenic organisms peripheral neuritis is not uncommon it *may for* example, be provoked by a suppurating wound. I can recall several cases of multiple neuritis associated with *empyema and* cases of neuritis from so simple a cause as pyorrhœa alveolaris have been described by Dr Hunter and *Mr Baldwin Hoyes.*[8] The neuritis in my patients was more or less generalised but I may state that *Fournier*, Raymond, and others have directed attention to the occasional development in urethritis of localised forms of the *affection* limited to the sciatic, crural, or cranial nerves and causing neuralgias or paralyses. I once met with *facial* paralysis in a youth with gonorrhœa, but was not able to satisfy myself that the paralysis depended in any way on the urethral disorder

It should be borne in mind that cerebral symptoms such *as hemiplegia* and aphasia, due to embolism, following endocarditis or phlebitis may develop during the course of *gonorrhœa.* I may now relate my first case, for the notes of which I am indebted to Dr O B Stewart.

CASE 1 —The patient a man aged 48 years, was admitted to the Royal Infirmary, Liverpool under my care on Feb. 13th 1894 He had always been active and thoroughly temperate. He had suffered from typhoid fever at the age of 28 years. There was no history of syphilis but the patient had had gonorrhœa at the age of 28 years and again a month before admission. There was no history of injury or of exposure to cold or to any toxic agent. The patient's father died at the age of 70 years, probably from cancer his mother who was asthmatic, died at 65 years of age and his only brother and sister were in good health On Feb. 3rd he had noticed some weakness in walking—a difficulty in raising his feet and feebleness in the knees with some tingling in the feet. The following day the loss of strength had increased and he staggered there was tingling in the hands. On the third day he could stand only with support. On that day I saw him with his medical attendant, Dr Dunn There were great weakness of all the muscles of the lower limbs and almost complete paralysis of the muscles of the anterior tibio-fibular region. Sensation was normal there was no pain and knee jerks and plantar reflexes were absent. He could just stand if supported. On the fourth day of the disease the hands became weak and in a day or two the muscles of the arms and trunk were involved and he took to his bed Ptosis developed on the 9th the day before he entered the hospital. The urethral discharge had been somewhat profuse, but had almost ceased before the present illness began and on admission it was not noticed

The patient was tall (6 feet 2 inches) and thin. His features were asymmetrical and the lobes of the ears were ill-developed—i.e. he bore the marks of hereditary degeneracy In bed he was perfectly helpless being unable to move his head or to turn or to raise himself. There was no complaint of headache or other pain and the memory was good Owing to double ptosis the eyes were *half* closed, the pupils were equal (3 5 millimetres) and reacted normally to light and to accommo*dation.* There were nystagmus of the left eye when directed far to the left and paralysis of the internal rectus of the right eye. No affection of the lips or tongue was present. The patient swallowed well and his speech was normal His arms were extended by his sides and his fingers were flexed on the palms. The strength of grip was three pounds the power of extension of the fingers being slight He was just able to flex and to extend the forearm at the elbow and could *only* approximate the thumb to the first and second fingers. He could flex slightly and extend the hands at the wrist and also partially pronate and supinate them. He *could* not abduct his arms from his sides. There was evidence of great weakness of the deltoids the sterno-mastoids, the levator anguli, and other muscles of the neck and shoulders and *he could* not shrug his shoulders or move his arms from his sides or turn his head. The tendon *reflexes* were absent A subjective sensation of pins-and needles" which was felt in the hands was aggravated when *they* were *rubbed* together There was some weakness apparently of the lower intercostal muscles as the respiration was largely *diaphragmatic* with some retraction of the lower part of the chest. The respirations were 20 and the respiratory sounds were normal. The legs were extended and flaccid the feet were extended, the plantar arch was exag*gerated*, the *first phalanges* of the *toes* were extended and the distal phalanges were flexed (indicating *paralyses* of the interossei and lumbricales). The patient could not flex his feet or move his toes nor could he raise his heels off the bed, but he could draw them up for a short distance on bending the knees and could adduct the limbs to some extent, but could not abduct them. Sensibility of skin was normal. Knee jerks and plantar and all superficial reflexes were absent. The heart was normal, the pulse was 80 and normal and the temperature on the morning of the day of admission was normal in the evening it was 99 4° F The tongue was furred and the bowels had not acted for five days There was no enlargement of the spleen or of the liver The urine, which was passed with some difficulty, was normal.

On the night after admission the patient was very restless and slightly delirious, constantly desiring his limbs to be moved and complaining of a feeling of pressure round the umbilicus and also of thirst. The feet felt, he said uncomfortable if left long in one position but were free from pain. The respirations chiefly abdominal were 24 the voice was somewhat weak and the pulse was 84 The patient complained of excessive thirst. He passed urine once involuntarily He was ordered salicylate of soda, mercurial inunctions, and counter irritation by mustard over the spine. His symptoms became much aggravated during the next few days. On the 17th the respirations, which were entirely abdominal, were 34 and the pulse was 120 He spoke with effort. He became very noisy at night imagining that he was being pricked with needles and that a cold wind was blowing over him and he was delirious during the day talking incessantly complaining of being stabbed and pricked and galvanised was suspicious and feared that those about him had daggers. Hyoscine was administered and on subsequent occasions morphia. The limbs became weaker the paralysis of the left arm and leg being almost complete. He was just able to flex the fingers of the left hand and to move the right foot. The ptosis became absolute, the eyelids being fastened together by secretion On raising the lids it was observed that he could not direct his eyes upwards, downwards, or inwards but outwards only The pupil remained as before 3 5 millimetres. The tongue was dry thirst was incessant, and the temperature was normal in the morning and almost invariably a little up at night (99 4°) till the 21st. Urine and fæces passed involuntarily the bladder emptying itself when very slightly distended The sphincter ani relaxed on examination. A little later the patient refused his medicine. He had delusions that he was being poisoned that the water given him was narcotised and that he was being stabbed and murdered or set on fire. The restlessness and thirst continued. A bedsore appeared on the sacrum and ecchymosis formed on the heels and between certain toes that were in close contact He was put on a water bed. The gonorrhœal discharge became noticeable and pus was found in the urine with a small amount of albumin. Gonococci were detected in the pus. Examination of the blood gave a negative result.

Five days after admission he became rational and talked about his recent delusions, remembering them but not being able to account for them. He took a very despairing view of his condition. Respiration had improved and the voice was strong. He stated that there was a "flannelly" feeling in the hands, also an aggravation of the old sensation of "pins and needles," and that the legs felt as if they had been bruised. There was then some tenderness of the calves and over the external popliteal nerve. There was much loss of sensibility to interrupted current, especially over the extremities, also some loss of sensibility to heat and to cold, and a gentle touch over the fingers and toes was not recognised. There was some analgesia also to pricking over the same parts. About this time any attempt to move the right arm—i.e., the better of the two limbs—caused tremor from contractions of the pectoralis major. There was also some tremor of the muscles of the arm when at rest and of the facial muscles. On the 22nd, after a night of pain in the left knee and ankle, there was considerable effusion in the knee which became tender but not red. This condition of the knee lasted for five days. Early in March atrophy of the muscles was apparent and was especially marked in the extensors at the back of the forearm the thenar and hypothenar eminences, the deltoids and pectorals, the muscles of the thighs, the flexors of the feet, and the gastrocnemii. The tremor continued. There was mechanical irritability of many muscles. On March 5th in the right arm the long extensors of the thumb reacted to the faradic current, but the extensors of the fingers did not, the small muscles of the thumb reacted. The extensors communis and indicis did not react. Several muscles gave reaction of degeneration, such as the extensor communis of the right and left arms and the tibialis anticus and extensor communis of the right leg, while no reactions were obtained over the same muscles of the left leg. Improvement was first noted on the 6th, when there was an increase in power of flexing the forearm and more strength of grip. There was also some ability to flex, to extend, to abduct, and to adduct the feet, but inability to move the toes. On the 8th the patient could flex the toes of the right foot and a day or two afterwards those of the left foot. By the end of March the ptosis had disappeared and the movements of the eyeballs were normal, though the patient had double vision if he looked fixedly at anything for a long time. Tested with the dynamometer early in April the strength of grip of the right hand was 20 pounds and of the left hand 35 pounds and on April 24th the former equalled 30 pounds and the latter 45 pounds. The patient was still confined to bed and could just stand alone and take a few steps with support. There was loss of power of the extensor communis, the peronei, and the tibialis anticus muscles. The toes felt numb on standing. There was still slight tenderness over the calves, the arms, and the thenar eminence. Paralysis and wasting of the extensors of the hands were still marked, the patient being unable to feel small objects held between the fingers, and he could not button his shirt. He left the hospital on June 7th and a few weeks afterwards had perfectly recovered.

[8] The Dental Cosmos January 1902.

The ascending paralysis did not follow the usual course and prove fatal through bulbar troubles and during the later period of the illness symptoms appeared which gave us a fuller insight into its nature. For convenience of description my patient's disorder may be divided into two periods, in the earlier the symptoms were those of ascending, or Landry's, paralysis, and in the latter those of multiple peripheral neuritis. The onset of the affection was insidious and was unattended by pain or high fever. The patient only experienced a difficulty in lifting his feet on his way to business. The loss of voluntary muscular power was first noticeable in the distal parts of the lower extremities and the paralysis by the fourth day had involved the muscles of the hands and in a day or two those of the trunk, the arms, and the neck. The knee-jerks and the plantar reflexes were lost on the third day, perhaps earlier, and sensory symptoms were not marked. The faradic irritability of the paralysed muscles was preserved for some weeks and no derangement of the action of the bladder or of the rectum was observed till the eighteenth day (Feb. 21st). On the fourteenth day the respirations and the pulse were quickened, the respirations being 32 and the pulse 120, and the voice was weak. These symptoms pointed to the possible implication of the bulb and its nerves, but the diaphragm did not seem to be affected, there being evidence rather of weakness of the lower intercostals. Although his life at this critical period was menaced the derangement of respiration and circulation gradually lessened. The levator palpebræ and all the external muscles of the eyeballs were paralysed, with the exception of the external recti; there was, therefore, suppression of the functions of the third and fourth nerves, but the sixth nerve and the fibres in the third for accommodation and for the reflex action of the iris escaped.

It is not usual for the facial or ocular muscles to be implicated in multiple neuritis, but they do not invariably escape. The orbital and facial nerves are more frequently involved in Landry's paralysis and the serious forms of toxæmic paralysis, as in post-diphtheritic neuritis, than in the polyneuritis of alcohol and of the organic poisons. It is worthy of note that the sixth nerve—more commonly affected in diphtheritic paralysis than any other orbital nerve—was not implicated. Raymond[9] and others describe cases of toxæmic neuritis with implication of the cranial nerves. I have seen Landry's paralysis accompanied with ophthalmoplegia and blindness and also with facial paralysis.

The peculiar character of the orbital paralysis originated in one of two ways—either there was a lesion of the nucleus of the fourth nerve and the adjoining posterior part of the nucleus of the third nerve (the anterior part of this nucleus, devoted to the innervation of the iris, and the nucleus of the sixth nerve not being involved), or the paralysis was due to a neuritis sparing the sixth nerve and those fibres in the third nerve concerned with the functions of the iris but implicating all the other fibres in the trunk of the third nerve and also involving the fourth nerve. We meet with a similar distribution of paralysis in certain cases of ophthalmoplegia externa, undoubtedly due to degeneration of the nuclei of the nerves concerned.

From our knowledge of the anatomical relations of the nuclei in question it can be conceived that a lesion may be so limited as not to extend forwards to the anterior part of the third nucleus or backwards to the distant sixth nucleus, but we can hardly imagine that the trunk of the third nerve could be involved in an inflammatory process which, while it annihilated the functions of the greater part of the fibres, left the functions of the lesser part entirely intact. I am inclined to believe, therefore, that the peculiar distribution of the orbital paralysis was due to a dynamical disturbance of the fourth nucleus and of part of the third nucleus. Any lesion must have been slight, as the ophthalmoplegia was of short duration, improvement in the condition of the muscles of the eyes being manifested early in March and their restoration to power being complete before the end of the month, at a time when the limbs were still paralysed. I may also say that lesions of the nuclei on the floor of the fourth ventricle are not uncommon in the paralyses from toxæmias.

Much difference of opinion has prevailed as to the nature of the lesion of the nervous system in Landry's paralysis, but the view that best explains my case and coincides at the same time with the convictions of a great proportion of modern writers is that the disease is a toxic or infectious process involving the peripheral motor neuron. Sometimes the ganglion cells are more particularly involved and at other times the peripheral fibres. We might anticipate that these elements of the neuron would be affected by the same toxic agents, as they are functionally and anatomically related. There is evidence in the cerebral symptoms, delirium and delusions, that the cells of the cortex suffered and therefore that the action of the poison was not limited to the nerves. But the derangement of the ganglion cells was slight and fugitive and unattended with destructive changes.

Vulpian has demonstrated that an experimental myelitis may be set up capable of ending in resolution and of leaving no trace in the cord or even in the ganglion cells, but sufficient to produce degeneration in the peripheral nerve fibres. Erb, indeed, has always held that functional disturbance of the atrophic centres in the anterior cornua can induce appreciable anatomical changes in the motor apparatus—nerves and muscles. Raymond believes that amyotrophic paralysis in relation with multiple neuritis and amyotrophic paralysis of manifestly spinal origin are similar morbid conditions and develop under the influence of the same causes, and holds that the dominant element in the pathology of these amyotrophies is an alteration, dynamical or structural, of the special trophic centres. In support of this view he appeals to experimental researches similar in character to those conducted by Vulpian.

---

[9] Clinique des Maladies du Système Nerveux.

Landry's paralysis acute anterior poliomyelitis and polyneuritis may develop under the influence of very different causes, but almost always these causes come under the categories of intoxications or infections, one or other of these disorders is excited according as the *deleterious* agent attacks the whole neuron, the ganglion cells, or the nerve trunks.[9] The ganglion cells and nerve fibres may in different cases of ascending paralysis be involved in varying degree—one may be of poliomyelitic and another of *polyneuritic type.* If the poisonous agent attacks the neuron with *great violence* rapid suppression of its functions follows—i.e. *motor* paralysis—and the neuron may be disorganised throughout its length. In these conditions the degenerative changes in the ganglion cells are precocious and at least equal in intensity to those of the axis cylinder and its envelopes. If the deleterious agent acts in a less brutal fashion the peripheral nerves alone suffer in the first assault, since the axis cylinder is the most fragile part of the neuron especially in its more distant portions, in these circumstances a peripheral neuritis results. Or, lastly the toxic substance acts deleteriously on the whole neuron—only the changes which follow in the cells are transitory but in the peripheral nerves they persist for a longer period and their intensity is the greater at the distal extremities of the nerves. This was, I believe, the pathological condition developed in my patient under the action of the toxin of gonococcus or possibly under that of a pyogenic coccus associated with it; in my patient there was probably a *cellulo-neuritis*, the latter preponderating

In some cases of *ascending* paralysis there is ample evidence that the ganglion cells have succumbed to the action of the *irritant—poliomyelitis* characterised by exudation, vascular *lesions* and destruction of the cells of the anterior cornua. In other instances the pathological appearances point to a reaction of a less violent character—chromatolysis *discolouration* of nuclei and dissolution processes. *Without the delicate* methods of staining now at our command the latter anatomical changes would not be perceived and a cord from a fatal case of Landry's disease would if these more minute lesions alone were present, appear normal. I believe that in my case the ganglion cells of the anterior cornua suffered to *some* extent, but not in a degree to cause disorganisation, for a destructive lesion of these trophic centres would have been attended with irrecoverable atrophy of their peripheral nerve-fibres and permanent paralysis and shrinking of certain muscles. Serious implication of the cells *of* the lower neuron or anterior poliomyelitis would have been attended with symptoms of a different character In a poliomyelitis there is usually more or less marked constitutional trouble, the motor power in the affected muscles *falls rapidly* so that the paralysis is as complete in from 24 to 48 hours as it is likely to be, the paralysis is not regular in its distribution, one or more limbs or certain muscles of the limbs involved escaping recovery is rapid regression beginning in from seven to 14 days but it is rarely perfect, some muscles being left in a useless and wasted condition. In my patient the paralysis attained its maximum in from 14 to 18 days the muscles of the four limbs and trunk were symmetrically involved, restoration was much protracted, occupying over four months, but it was perfect.

It may be difficult to differentiate the affections of the lower motor neuron but the attempt should be made to distinguish cases where the motor cells of the neuron are the seat of a gross lesion in part irreparable from cases where a similar lesion interests only the peripheral nerves for an acute anterior poliomyelitis, if not mortal usually leaves irreparable injury behind it, whereas a multiple neuritis is almost always curable.

In a *few* cases of ascending paralysis a cause cannot be discovered. Some cases have developed after exposure to cold or subsequently to over-exertion and therefore may have originated in an auto-intoxication In the great majority of instances the source of the affection in an intoxication or an *infection is* pretty obvious It has followed arsenical mercurial, carbon monoxide, carbon bisulphide, and alcoholic poisoning and has occurred during the course or the convalescence of the following diseases influenza, typhoid fever variola, and syphilis it also has followed the bite of a rabitic dog and what interests us more particularly is the fact that it has been associated with infections by the pyogenic cocci and by the gonococcus. The experimental researches of Molchenoff are of interest in their bearing on the question of gonorrhœal affections of the *nervous system* He[10] demonstrated that the toxins or cultures of the gonococcus *injected into* the pleura of guinea pigs or rabbits produced lesions of the cells of the anterior cornua and cerebral cortex, with degeneration *of the peripheral* nerves at the end of three weeks. Roger had previously shown *that the toxin* of *streptococcus* exerted a pernicious action on the lower motor neuron. *Professor Raymond*[11] publishes a case of gonorrhœal polyneuritis with symptoms closely resembling those of my patient, ascending paralysis certain slight sensory atrophy and facial paralysis.

Derangement of the *functions* of the bladder and rectum are very rare in multiple neuritis but not uncommon in *Landry's* paralysis, in a fatal case of ascending *paralysis* which I recently attended with Dr A. Craigmile of Liscard *retention of* urine was one of the earliest symptoms. The retention of urine in the case under discussion was not due to weakness of the abdominal muscles as it was followed by *incontinence* and also by involuntary discharge of *fæces* and relaxation of the sphincter ani was found on examination. These troubles continued for a few days only *from* March 1st to 5th, and about the same period a bed *sore formed* they depended on a slight neuritis of certain trunks *of the cauda* equina or on dynamical disturbance of their nerve centres, the lesion of the nerves if it existed, *must have been of a* very trivial nature.

The *second* period of this patient's malady, when the symptoms of peripheral neuritis became pronounced may be quickly disposed of. The neuritis was severe as there was considerable wasting of the muscles of the extremities and of the pectorals and more especially of the muscles so commonly particularly implicated in the affection, the flexors *of* the feet and the extensors of the hand The mechanical irritability of these muscles was marked and they gave the reaction of degeneration. The knee-jerks and superficial reflexes were lost from the first There were not the pain in the extremities and the great tenderness of nerve trunks and muscles so commonly found in the peripheral neuritis of alcohol and arsenic—an indication that the sensory fibres of the nerve trunks were not severely implicated. A similar selective action is exhibited in lead and sometimes in alcoholic and other *forms of neuritis* when with much motor disturbance there is little or no sensory trouble. Improvement, as in most cases of polyneuritis was tedious, the derangement of the sensibility of the fingers and toes became rather more pronounced in the later weeks of his illness. Though the neuritis occasioned little pain it seemed to occasion cutaneous impressions of sufficiently disagreeable character to give a direction to his delirium and delusions awakening ideas of pricking burning stabbing &c.

I will not attempt to explain why the urethral discharge ceased at the advent of the paralysis and returned as the nervous troubles lessened you will probably have met with the same modifications of the local trouble in other cases of general gonorrhœal infection—as on the development and decline of gonorrhœal arthritis. In a case of fatal gonorrhœal endocarditis recently under my notice, following on a urethritis and severe arthritis of one knee, the urethral discharge ceased at the onset of the joint trouble and this in its turn was much modified as the cardiac symptoms became pronounced. The temperature was never high but was slightly raised in the evening for about 10 days The joint trouble could *hardly* be due to anything but the urethritis, there being no evidence of rheumatism or gout, and was therefore regarded as an indication of gonorrhœal infection.

My next case may be described in much fewer words

CASE 2.—The patient, aged 17 years, was admitted into the Royal Infirmary on March 6th 1894 complaining of weakness of the legs His family history was good. The only sickness which he had suffered from was influenza in the year 1893. He was liable to migraine. He was very temperate and there was no history of rheumatism, of over fatigue, or of injury and no evidence of exposure to any of the chemical or organic poisons He had had gonorrhœa for two months. A month after the onset of the urethritis he suffered from pain in both knees and in one elbow but did not notice any swelling A day or two afterwards his feet tingled a little and his legs gradually became weak so that for 14 days before coming to the Infirmary he was obliged to stay at home. He was a well nourished, healthy-looking youth. He walked with difficulty, holding on to a bed near him, and lifted his feet high to prevent the toes from dragging. He could stand with his eyes closed. There were decided weakness of the flexors and extensors of the leg and great weakness of the flexors of the feet. Sitting with the leg at a right angle to the thigh he was unable to raise the fore part of his feet off the floor. There was no pain on compressing the calves. The knee-jerks and plantar reflexes were absent. The cremasteric and abdominal reflexes were lively. There was some analgesia of the whole surface of the trunk, the face, and the limbs, which was most marked on the left side, and there was tremor of the hands and lips and closed eyelids. There was some restriction of the colour field, especially of the left eye. The taste was somewhat impaired and he could not detect solution of quinine on the tip of the tongue. The sense of smell was normal. There was pain occasionally under both nipples. The upper extremities, the electrical reactions, and the pulse (114) were normal. The apex beat was normal in site. There were systolic murmurs, probably functional, at the apex and the pulmonary areas. The temperature was usually normal night and morning, sometimes touching 100° F., at other times 99°. The urine was normal excepting for a little pus; the pus cells contained gonococci. Cultures of blood taken on the 15th revealed nothing. He was ordered bicarbonate and citrate of potash at first and subsequently a tonic with massage. He was able to walk well at the end of six weeks and was discharged on April 20th.

---

[10] Archives Russes de Pathologie, 1899 tome viii
[11] Progrès Médical, 27 Juillet, 1901

The symptoms here pointed, in my opinion, to a neuritis chiefly involving the motor fibres of the peripheral nerves of the lower extremities and causing muscular weakness and pseudo-tabes. He also had some of the stigmata of hysteria—namely, general analgesia most marked on the left side, some restriction of the visual fields, tremors of the hands and eyelids, some impairment of taste, &c. He was undoubtedly hysterical, but, in my opinion, the paralytic troubles were not due to this disorder. Hysterical paralysis is usually associated with much loss of sensibility of the limbs affected; the sensation in this lad was no more impaired over the legs than elsewhere. The absence of the knee jerks, the loss of the motor power of the flexors of the feet, and the tingling in the toes, pointed to a neuritis. Like the other patient, there was, for a certain period, joint trouble indicating general gonorrhœal infection. In both cases the discharge was not perceptible on admission but required treatment subsequently. Both patients were of neurotic temperament; the patient in the second case suffered from migraine and was hysterical. The other patient had a mother who was an asthmatic subject and he bore the marks of degeneracy. In this neurotic condition we have the predisposing cause, rendering their nervous tissues susceptible to the action of toxins. Raymond observes, "All intoxications seem to me capable of developing a polyneuritis in a subject tainted with a neurotic constitution."

I may point out that it is not possible to obtain positive proof of the causal relation of the gonorrhœa and the paralysis in my cases or in similar cases ending in recovery. The probability of the correctness of the diagnosis rests upon the following facts. Peripheral neuritis is invariably due to some intoxication, often to bacterial infection. Many cases of peripheral neuritis have been set down to gonorrhœal infection, and experiment has indicated that the toxin of the gonococcus is capable of exerting a morbid influence on the nervous tissues—central and peripheral. In my patients there was evidence of gonorrhœal infection in the joint trouble and no other source of intoxication could be discovered. I recognise this to be a weak point in the argument, because, in some few cases of multiple neuritis, poliomyelitis, and Landry's paralysis no origin of intoxication can be recognised.

Liverpool.

BARTON REGIS WORKHOUSE.—The Right Hon. Sir John Dorington, Bart., M.P., formally opened, on Sept. 18th, the new workhouse of the Barton Regis union, which is situated at Westbury on Trym, near Bristol. The institution stands on 13½ acres of land, will provide accommodation for 110 inmates and 24 casuals, and has been erected at a cost of £33,000. The infirmary contains two wards of six beds each, two smaller wards of four beds each, and also two isolation wards of one and two beds respectively.

OPERATIONS UNDER ANALGESIA PRODUCED BY INTRA-SPINAL INJECTIONS OF COCAINE.

By H. LITTLEWOOD, F.R.C.S. Eng.,
SURGEON TO THE LEEDS GENERAL INFIRMARY AND LECTURER ON PRACTICAL AND OPERATIVE SURGERY IN THE YORKSHIRE COLLEGE, VICTORIA UNIVERSITY.

THE article in THE LANCET on anæsthesia produced by intra spinal injections of cocaine which appeared early in 1901[1] induced me to try the method, and the annotation in THE LANCET of April 12th, 1902, p. 1051, suggested to me that probably my experiences might be interesting to other surgeons. My house surgeon, Dr. A. Morton, has very kindly collected my cases and abstracted the notes which I now offer for publication. In addition to these are the notes of a case operated on by my colleague Mr. Ward who has kindly allowed me to publish it. After following the detailed instructions given in your article I had practically no difficulty in puncturing with the needle and introducing the fluid, the resistance offered by the subflavus ligament was readily appreciated, and pushing the needle a little further the cerebro spinal fluid soon began to flow in small drops. After injecting the cocaine I injected a little sterilised salt solution to wash out the needle to be quite sure that I had introduced the full dose. I do not think that I have ever been more impressed in my life than I was with the first case and I believe that all who saw the operation were equally impressed. It was difficult to realise that within a few minutes of introducing a third of a grain of cocaine into the spinal canal one could deliberately amputate through the knee-joint, the patient being conscious all the time and yet not feeling any pain. In all the cases with the exception of the one operated on in April, 1901, it answered admirably. This patient was a very nervous man and I think it was more from fear than from pain that he cried out. I was not quite satisfied that I had given him a proper dose and the solution of cocaine had been twice sterilised, which may have altered its composition. The faintness of some of the patients was a little alarming; two or three of the patients I gave a hypodermic injection of 10 minims of liquor strychninæ before the injection, and this I think, had a good effect. In your article you refer to the conservatism of English surgeons. One can well understand this attitude towards anæsthetics, which are now, as a rule, so well given and with such excellent results both for patients and surgeons that any new methods must have a great deal in their favour before a trial is ventured on. I was really induced to try the method in the first case because I felt a general anæsthetic of any kind would be a serious factor in the case and I certainly believe there are some cases where this means of producing analgesia must be useful and valuable. I have not operated on any case by spinal cocainisation since April, 1901, and I may fairly be asked, Why? I do not feel it is so immensely superior to other methods; my last case was not quite a comfortable experience; the fact that the patients are conscious of what is going on is to some very distressing, and I think I rather shirk the dual responsibility of acting both as anæsthetist and surgeon. The cases are arranged in chronological order.

CASE 1. *Senile gangrene of both feet; Stokes's amputation, right side.*—The patient was a man, aged 58 years. Operation was performed on Jan. 24th, 1901. Intra spinal injection of a quarter of a grain of cocaine was given. Operation was commenced eight minutes after the injection. The patient felt no pain during the operation, although he felt a vibrating sensation when the bone was sawn. The pulse increased from 96 to 108 and was intermittent. He sweated profusely towards the end of the operation. Respiration was laboured. He retched a little and tried to vomit, but this gradually passed away. About three-quarters of an hour after the operation he began to recover sensation in the stump. He took food soon after the operation. For the first week he appeared to be making good progress, the stump healing well. On Feb. 4th the patient died suddenly without any previous indication of failing except the pulse, which had been feeble and irregular both before and after the operation. His peripheral arteries were most of them rigid and calcareous.

---

[1] THE LANCET, Jan. 12th, 1901, p. 137.

CASE 2 *Senile gangrene of the foot Stokes's amputation*.—The patient was a man, aged 43 years Operation was performed on Jan. 28th, 1901. Intra spinal injection of one-third of a grain of cocaine was given. There was partial analgesia to pricking three minutes after injection and total analgesia to pricking four minutes after injection, not only in the lower limbs, but to a point two inches above the umbilicus. Operation was commenced seven minutes after injection. The patient felt practically no pain during the operation a violent contraction of the thigh muscles when the great sciatic nerve was divided caused slight pain The sawing of the femur and patella caused a jarring sensation but no pain. The patient was quite quiet during the whole of the operation. His colour remained unaltered and his breathing undisturbed. The pulse fell from 120 to 80 and became less in volume. There was slight sweating but no vomiting The pupils became smaller After the operation was over he complained of thirst and he had a few ounces of water this he vomited back again in a few minutes During the rest of the day the patient slept quietly He complained of some pain at times and tingling in the legs. In the evening he had two slight epileptic seizures. Between and after these he was drowsy He made a good recovery

CASE 3. *Hydrocele of the tunica vaginalis, radical cure*.—The patient was a man, aged 55 years Operation was performed on Jan. 28th 1901 Intra spinal injection of one-third of a grain of cocaine was given In about five minutes from injection the patient said he felt an advancing numbness in the limbs and a minute later he could not feel pain in the scrotum when it was being pinched, although he could feel it being touched. Operation was commenced seven minutes after the injection The patient felt no pain during the whole of the operation He felt the fluid from the hydrocele trickle down his thigh. During the operation the patient became ghastly white and the pulse was very rapid and almost imperceptible at this time he felt very sick but spoke when questioned quite naturally and said that he felt no pain anywhere only a little tightness across the chest and a sinking feeling in the epigastrium. He was given 10 minims of liquor strychninæ hypodermically the pulse re-acted immediately and became slower and fuller though the patient was still very pale. General sensations, including sensations of heat and cold (which were tested), were retained he could feel no pain from a pin prick, although he knew that he was being pricked by a pin. He was given a little brandy at the end of the operation This was promptly vomited and he continued vomiting and retching for a few minutes after this. An hour after operation the pulse was 98, regular and less easily compressible, pallor was much reduced He was having some tea. He complained of a little tightness across the chest. The skin was clammy and perspiring He had clonic spasms in the lower extremities.

Notes by Dr W H M Telling.—Three minutes after the commencement the pulse was 88 and numbness was felt in the soles of the feet. Four minutes after the commencement numbness was felt in the knees. Five minutes after numbness was felt in the scrotum. Eleven minutes after an incision was made The pulse was 68. The patient got rapidly paler collapsed, and the pulse could not be felt. Fourteen minutes after ten minims of strychnine were injected hypodermically Fifteen minutes after brandy was given by the mouth, the pulse was better (64) Eighteen minutes after the operation ended The patient vomited a little. He made a good recovery

CASE 4 *Inguinal hernia radical cure Bassini's operation*.—The patient was a man, aged 34 years. Operation was performed on Jan. 30th, 1901. Intra spinal injection of one-third of a grain of cocaine was given The patient was quite conscious during the whole time Although quite free from pain he could feel the touch of anything Two minutes after commencement the pulse was 100 Three minutes after numbness was felt in the toes Five minutes after numbness was felt in the knees. In six minutes the scrotum was analgesic Seven minutes after the pulse was 80. Eight minutes after an incision was made the patient felt the cutting sensation but no pain. Nine minutes after the pulse was 44 The patient felt sickly and hot, his lips were paler and he vomited with some straining Twelve minutes after the pulse was 52. Fourteen minutes after the hands were numb and he was sweating slightly Fifteen minutes after he was sweating profusely and there was an aching sensation at the site of the wound. Seventeen minutes after the pulse was 62. Twenty five minutes after the pulse was 88 Twenty six minutes after the patient winced slightly and complained of sensation of weight. Thirty minutes after he felt the pulling of tissues, when the deep stitches were put in. Thirty three minutes after the pulse was 88 and the operation was ended He felt the superficial stitching but it was not painful Sensation to heat and cold was lost. Although the patient got collapsed slightly and faint when the pulse was slowest there was never any real anxiety as to his condition. Vomiting improved the pulse. The patient had a chop for dinner. He made a good recovery

CASE 5. *Radical cure of inguinal hernia Bassini's operation*.—The patient was a man aged 26 years. Operation was performed on Feb. 4th, 1901. Intra spinal injection of a quarter of a grain of cocaine was given. A few days after the operation the patient developed acute pneumonia, otherwise he made a good recovery He had no pain or inconvenience during the operation.

CASE 6. *Varicose veins of the lower extremities*.—The patient was a man aged 30 years. Operation was performed on Feb. 5th 1901 Intra-spinal injection of one-third of a grain of cocaine was given. During the early part of the operation the patient complained of a little pain but after a slight nausea this was unnoticed. Portions of the veins of the right lower extremity were dissected out. The operation was inconvenienced by clonic spasm which affected the muscles of both thighs. Two hours after the operation the patient was insensible to pain in the lower extremities and was numb as high as the fourth costal cartilage. He did not feel the pain but only the pressure of the prick of a needle in this area. The skin could be pinched tightly while pressure on the testicles was painless. Sensation to cold existed. Five or six hours after the operation the patient complained of aching in the small of the back. Clonic spasms in the thigh muscles were also present these gradually passed off. On Feb. 14th the left internal saphenous vein was ligatured under an intra-spinal injection of one-third of a grain of cocaine. The patient had no pain and made a good recovery

CASE 7 *Varicose veins of the lower extremity excision*.—The patient was a woman, aged 28 years. Operation was performed on Feb. 11th 1901. Intra spinal injection of one-third of a grain of cocaine was given at 10 39 A.M At 10 46 operation was commenced. There was no sign from the patient. At 10.50 the face and hands sweated profusely there was retching and the pulse was 60 regular and full. At 10.52 the pulse was 62, regular and full. At 10 53 the sweating had considerably diminished The patient retched at intervals. At 10.55 the pulse was 70 and the patient drank a little water At 10 57 the pulse was 100, not quite as full. At 10 58 the pulse was 84 The feeling of sickness was much relieved by water Throughout the operation the patient constantly declared that although she felt something there was absolutely no pain. At 11 0 the operation was finished. The pulse was 84 regular and the fulness was increasing There was slight sweating but the mucous membranes and finger nails had remained of a good colour throughout. The patient was smiling and quite cheerful. At 11.2 the skin was quite dry The pulse was 76 and full The patient had her meals as usual after operation. She suffered from headache in the afternoon after the operation, also for two or three days following She made a good recovery

CASE 8. *Radical cure of femoral hernia*.—The patient was a woman aged 36 years. Operation was performed on Feb. 11th 1901. Intra spinal injection of one-third of a grain of cocaine was given. The operation was commenced seven and a half minutes after the injection and was completed at the end of 25 minutes. The patient had entire loss of sensation of pain and seemed hardly conscious of pressure or weight She perspired freely and felt very hot. The pulse at the commencement was 96 per minute and varied between 100 and 110 during the operation. The patient neither vomited nor felt sick and had no sensations of tingling either before or after operation. She had a drink of water during the operation She made a good recovery

CASE 9 *Radical cure of double inguinal hernia Bassini's operation*.—The patient was a man, aged 44 years. Operation was performed on Feb. 11th, 1901 (left side). Intra spinal injection of one-third of a grain of cocaine was given. This patient asked to be operated on under cocaine, as his experience of ether was unsatisfactory and the patients in the two beds on his left had been operated on by this method. The patient had no pain during the operation but was sensitive to pressure. On the 25th the right side was operated on One third of a grain of cocaine was injected as before. The injection was not as successful as on the former occasion The patient felt pressure as he did on the left side and he had painful sensations when the needle was used for stitching, though the primary skin incision did not apparently trouble him at all He made a good recovery

CASE 10 *Senile gangrene of the foot, Stokes's amputation* —The patient was a man, aged 61 years Operation was performed on April 25th, 1901. Intra spinal injection of one third of a grain of cocaine was given This was not very successful, probably because the cocaine had been twice sterilised and the needle was not washed out with salt solution, so that the patient might not have had the full dose. He was a very nervous man and appeared to feel acutely some parts of the operation. It was difficult to estimate how much he really felt. His pulse was 140 throughout. He had no sickness He made a good recovery

CASE 11. *Gangrene of the leg* —This case was operated on by Mr Ward The patient was a woman, aged 43 years Operation was performed on Feb 20th, 1901 Intra spinal injection of one third of a grain of cocaine was given In 10 minutes there was complete analgesia in both lower extremities Amputation was done through the middle of the thigh After the operation 10 minims of liquor strychninæ were given hypodermically The patient vomited after the operation. The parts remained analgesic for about two hours The patient made a good recovery

Leeds

LEUCOCYTE ENUMERATION FOR ROUTINE WORK

BY WILLIAM G SAVAGE, B SC, M D LOND,

LECTURER ON BACTERIOLOGY, UNIVERSITY COLLEGE, CARDIFF

THE estimation of the number of leucocytes in the blood is acknowledged to be of great value and should be practised more frequently as a routine method of examination It will probably be admitted, however, that it is by no means as frequently, and as an every day practice, carried out as its value warrants This, I think, is largely due to the extra time and trouble involved in making a separate leucocyte count and to the considerably larger amount of blood required The method of enumeration advocated by most authorities is by means of the Thoma Zeiss apparatus, using the large special pipette provided for that purpose A diluting solution, such as very dilute acetic acid, is used to lake the red corpuscles Such a method necessitates a collection of the blood and an enumeration quite separate from that for the red corpuscles A distinctly larger quantity of blood is also required, and this in many cases is not obtained without considerable difficulty when it is remembered that pressure and other aids to blood flow must be avoided. Patients, particularly in private practice, object to the deep puncture required.

The object of this brief note is to call attention to the value of the method advocated by Stengel[1] and to give a convenient mathematical formula for the enumeration. In his article Stengel explains how the calculation can be made but does not give a convenient formula which is always available. The method is slightly less accurate than if a separate dilution of 1 in 10 is made, but is sufficiently accurate for routine work, and with a formula to save calculation the extra enumeration of the leucocytes occupies only a few minutes One collection only of blood is required, the red and white corpuscles being counted in the same preparation and only one pipette has subsequently to be cleaned, in this way a considerable amount of time is saved It has the advantage that if the white corpuscles are very numerous they can be counted on the squares in the same way as for red corpuscles Professor C S Sherrington has also pointed out the importance of counting both red and white corpuscles in the same blood preparation.

In brief the method is as follows Use a Thoma Zeiss small pipette—i.e., the one ordinarily used for red corpuscles —and collect the blood exactly as for the enumeration of red corpuscles except that the blood should always be collected up to the 1 0 mark and the dilution should be made with some coloured fluid such as Toisson's solution[2] or Sherrington's fluid The red corpuscles are first counted in the ordinary way To count the leucocytes, draw out the eyepiece until a diameter of the field of vision is just spanned by an exact number of squares Call this number x—i.e., x=the number of squares which exactly stretch across a diameter of the field of vision. The ruled squares need now no longer be taken into account but only the fields of vision Count the number of leucocytes in any recorded number of fields of vision, taking care that the fields do not in any way overlap The stained leucocytes can be readily distinguished from the red corpuscles Divide the number of leucocytes by the number of fields of vision counted to obtain the average number per field of vision Let this = y—i e, y = the average number of leucocytes per field of vision The larger the number of fields of vision counted the better Then, with the blood diluted 100 times, as recommended, the number of leucocytes per cubic millimetre = $\frac{5,600\,000\,y}{11\,x^2}$.

x and y only have to be determined and a simple calculation gives the result. Such a formula is available for any microscope and for any eyepiece, &c

A note on how the formula is obtained is appended

x = the number of sides of squares to go across the field of vision Each square is $\frac{1}{20}$ millimetre the diameter of the field of vision is $\frac{x}{20}$ millimetre, and the radius (r) of the field of vision = $\frac{x}{40}$ millimetre The area of any circle = πr^2, and the area of the field of vision = πr^2 $\pi = \frac{22}{7}$ (near enough for practical purposes) the area of the field of vision in questio = $\frac{22}{7} \times \left(\frac{x}{40}\right)^2$ The depth of blood in the countin cell is $\frac{1}{10}$ millimetre, the cubic capacity of the field o vision = $\left(\frac{22}{7} \times \left(\frac{x}{40}\right)^2 \times \frac{1}{10}\right)$ cubic millimetre y = the average number of leucocytes per field of vision—i e. in 1 field of vision = y leucocytes, in $\frac{22}{7} \times \left(\frac{x}{40}\right) \times \frac{1}{10}$ cubic millimetre = y leucocytes, and in cubic millimetre $\frac{7 \times 40 \times 40 \times 10 \times y}{22 \times x^2}$ leucocytes = $\frac{56,000\,y}{11\,x^2}$ (This is in the diluted blood.) The blood i diluted 100 times, in 1 cubic millimetre of the undiluted blood = $\frac{56,000\,y \times 100}{11\,x^2}$ leucocytes = $\frac{5,600,000\,y}{11\,x^2}$

Cardiff

BUPHTHALMOS, OR CONGENITAL HYDROPHTHALMOS[1]

BY GEORGE WHERRY, M.C CANTAB, F R C S

THREE cases of buphthalmos, or congenital hydrophthalmos, are here remarked upon

CASE 1.—In this case the patient was an infant with ver large and nebulous corneæ and rather blue sclerotics. Th pupil of one eye could just be seen The cornea measure across from 13 to 14 millimetres in each eye, but there w no conicity or local bulging

CASE 2.—The patient was a girl, aged 14 years, with larg nebulous corneæ 15 millimetres in diameter and wit nystagmus. The vision was greatly impaired—with both eyes together for distance about [illegible] with *movements of the head* and effort. She had been under observation all her life at long intervals and was first seen when 10 months old. No *accident or disease preceded the condition described.* The mother stated that her father and her husband's father were first cousins, and their respective mothers were sisters. She told me that she was not sure of the relationship on her husband's side in the previous generation but that of her four grandparents on her own side three bore the same name as herself originally

---

[2] Toisson's solution consists of methyl violet 0 025 gramme, chlori of sodium, one gramme, sulphate of sodium eight gramme glycerine 30 grammes, and distilled water 160 cubic centimetre The solution does not keep well It must be quite clear and should filtered just before use

[1] A paper read before the Cambridge Medical Society.

CASE 3—A specimen was exhibited of a right eyeball lately excised from a lad aged seven and a half years. The patient was a large boy with a big appetite The disease had existed from birth and had been under observation ever since. The cornea was large and *fairly* translucent and the coats were thinned and the eye gradually increased in size until discomfort and photophobia necessitated excision of the globe *The vision was entirely lost and the nerve could* be seen to be atrophied before operation. The cornea was about 15 millimetres across—according to Priestley Smith the normal cornea should measure from 11 to 12 millimetres It was only just possible to deliver the eyeball during the removal without cutting the outer canthus It measured 30 millimetres and 33 millimetres in long and short diameter The other eye (the left) had less than normal vision ($\frac{6}{18}$ partly) The cornea measured the extraordinary diameter of 14 millimetres and the eyeball appeared large, but there was no lack of lustre in the cornea and it only suggested an unusually fine eye. The pupil acted well to light and there was no tension. There was nothing remarkable in the family history

Buphthalmos, as in these cases, is a congenital disease, but it is quite possible to have a similar disorder in young subjects as a consequence of disease or injury *Treacher Collins has made observations which fully confirm* the opinion of clinical observers who consider the disease to be glaucoma but occurring in young subjects. The coats of the eye yielded under the intraocular pressure. The iris structures in the prenatal state failed to be separated from the cornea at the filtration angle, and the microscope revealed that this was not inflammatory in the first instance but a congenital failure.[2]

In treatment operative proceedings, sclerotomy or iridectomy have not proved satisfactory it would be best in most cases to use eserine, and in any case to avoid atropine. The patient in Case 1 is improving under eserine. In diagnosis the large surface area of the cornea with no injury or disease to cause stretching softening or opacity is the most important to notice. Here the keratometer of Priestley Smith is of great use in making the first observation and record. The unusual size of the left cornea in the lad who lost the right eye from this disease (Case 3) must be evidence that the mischief was symmetrical.

The cornea is the *most precocious* of all the structures of the body The eye generally may be said to take a precedence, and the cornea is the earliest part of the eye to attain *perfection. It is a most interesting fact* that the cornea attains its full size at five years of age (Priestley Smith) The corneæ are formed thus early and we look *through* the same *sized* windows at *five years of age* as we do when we attain to the age of 40 years. Very different is this from the growth of the crystalline lens which grows slowly and *steadily* through early life to old age and *this fact* has bearings on glaucoma of the middle-aged or senile eye. This precocity of the corneal growth has a most interesting effect on opacities and scars. Compare, for instance, the scar on the skin of an infant—a familiar instance is a vaccination scar which grows until the infantile mark has become in the adult arm a cicatrix of great size and usually is far larger than any subsequent cicatrices from vaccinations of later life. It has been well remarked by Sir James Paget that a scar the size of the little finger of the infant might grow *to* the size of the little finger of the adult. But in the face, which does not grow proportionally with the limbs, the growth in the scar is not so evident. On the cornea, as a non vascular structure the cicatrix is likely to become relatively smaller and in any case the opacity has little chance of growing to impair further the translucency of this most precious structure In fact, the opacity or cicatrix on the cornea does not grow at any time of life, on the contrary *it tends* to lessen in size and becomes less opaque The scar of a perforation in the infantile cornea, as in pyramidal cataract, is often extraordinarily slight and difficult to see in the adult, but if the iris be adherent and remain so the tissues are vascularised and the opacity is more dense.

Nebulous conditions of the infantile cornea, though they cause great anxiety are often serious not so much from the opacity which may prove transient, as from the various complications which result, as squint, nystagmus, and loss of retinal function. It is a serious matter to shut off light from the retina during the first years of life and the windows thus early opened must not be opened in vain. A cloudy cornea may clear up and yet leave the vision seriously impaired *The feeble vision of a squinting eye, when the* other eye does all the work shows the importance also of the stimulus of objects ignored by the squinting eye *(amblyopia from exclusion) The eye affected never learns* to fix an object or to see it clearly The eye moves with amazing rapidity under the stimulus of a flying object. Even nystagmus may be observed under certain conditions of experiment, as when flying objects are watched from the window of a travelling railway-carriage movements of the eye are produced which without such stimulus would be impossible

The foregoing considerations are put forward to show that, even if the buphthalmos be stationary as to the essential glaucomatous symptoms, from the point of view of an opaque or stretched cornea the disease is very grave and threatening The congenital condition described by Treacher Collins led to the progressive stretching of the eyeball from intraocular pressure and in Case 3 to the loss of the eye Richardson Cross[3] has related cases both of congenital buphthalmos and of buphthalmos when secondary to injury *or disease* The latter would be recognised by the same signs. It is well to notice that opacities of the cornea the result of hereditary syphilis are of the nature of interstitial *deposits* like *gummata* and rarely appear in early infancy but usually at the age of from six to 15 years—i.e. not until the cornea has attained its full size Here also considerable vascularity of the *cornea* is commonly associated. It is not difficult thus to exclude congenital syphilis from the diagnosis

The three cases above *mentioned at three stages* of growth from infancy to adult age illustrate very well the course of buphthalmos in its clinical aspect.

Cambridge.

A NOTE ON SYPHILIS IN RELATION TO LIFE ASSURANCE, WITH AN EXAMINATION OF 800 CONSECUTIVE CLAIMS

BY F PARKES WEBER, M.D CANTAB F R C.P LOND
PHYSICIAN TO THE GERMAN HOSPITAL, DALSTON; ASSISTANT PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR CONSUMPTION

PROFESSOR J W RUNEBERG[1] of Helsingfors in his *address* to the third Northern Life Assurance Congress, analysed a consecutive series of 734 deaths amongst persons assured by the Kaleva Company extending over the period from the foundation of the company in 1875 to the year 1897 inclusive. He came to the conclusion that 15 per cent. of the deaths were more or less brought about by syphilitic infection whilst *during the same period* 21 3 per cent. could be assigned to tuberculous affections and 10 per cent. to pneumonia. Thus syphilis according to Runeberg's estimation, ranked next *to tuberculosis in frequency* amongst the causes of death Moreover Björksten the medical director of the company found that of persons insured during the 20 years up to *1895* 12 6 *per cent* of those who gave a history of syphilis died, whilst the mortality was only 6 1 per cent. amongst those who denied infection. Out of the 734 deaths Runeberg *first selected* 84 which he considered might be regarded as to some extent the result of previous syphilitic infection most of them as syphilitic or post-syphilitic affections of the heart and central nervous system In not all of these cases, however, was there undoubted evidence of primary or secondary syphilis Thus, of the 22 cases of general paralysis in 11 cases a history of syphilis was given at the time of assurance and in five others medical evidence of syphilis was obtained, but in three there was a history of "soft chancre" only, and in the remaining three no evidence of infection was forthcoming In the following cases also a history of "soft chancre" only could be obtained a death from tabes dorsalis and cardiac valvular disease at the age of 30 years, a death from aortic aneurysm at the age of 37 years, fatal apoplexy at the age of 40 years, and deaths from "heart stroke" ("*Herzschlag*," syncope) at the ages of 35 and 50 years These 84 cases, however, constituted only 11 4 per cent of the total number of deaths from all causes Runeberg tabulated 47 other cases in which there was no history of syphilis but in which death occurred under the age of 50 years from "heart-stroke," cerebral hæmorrhage, or cerebral softening He argued that about 75 per cent. of these cerebral cases and about 50 per cent of the "heart-stroke" cases were probably in reality due to syphilitic disease of blood-vessels, and in this way he brought the number of deaths more or less caused by syphilitic infection up to 15 per cent of the total

---

[2] Transactions of the Ophthalmological Society of the United Kingdom vol xvi p. 348.

[3] Ibid vol. xvi., p 342.

[1] Ueber den Einfluss der Syphilis und die Sterblichkeit unter den Versicherten, Deutsche Medicinische Wochenschrift 1900 No 18 to No 20

Various objections may be raised against Runeberg's figures In the first place, in the cases in which a history of syphilis, or at least doubtful syphilis, was obtained and in which Runeberg considered the death to be more or less the result of the specific disease it may be questioned whether the actual cause of death ("heart-stroke," cerebral hæmorrhage, &c) was not in some of them altogether independent of the syphilis Furthermore, in regard to the cases without any history of syphilis but in which death occurred under the age of 50 years from "heart-stroke," cerebral hæmorrhage, or cerebral softening (thrombosis), was Runeberg justified in considering so high a proportion (75 per cent. of the cerebral cases and 50 per cent. of the cardiac cases) as probably due to syphilitic vascular disease? Was he justified in attributing all the deaths from general paralysis and tabes dorsalis to previous syphilitic infection? Was he right in supposing that the aortic aneurysm which caused the death at 37 years was of syphilitic origin?

Few will, I think, consider Runeberg wrong in regarding syphilis as a factor in all the cases of general paralysis and tabes It is not necessary to go as far as some authorities do and affirm, "No syphilis, no general paralysis or tabes," in order to admit, as I believe the balance of evidence forces us to, that general paralysis and tabes seldom or hardly ever occur in persons who have never had syphilis Overstrain, &c, are doubtless exciting causes of aortic aneurysm, but syphilis has long been suspected to be a predisposing cause [2] The disease shows a partiality for the classes of men (soldiers, &c) amongst whom syphilis is specially prevalent, and, moreover, the favourite age of incidence for aortic aneurysm is not the same as that for ordinary atheroma. Dr Thomas Hayden, out of 92 cases of aortic aneurysm analysed by him, found that 60 occurred between the ages of 30 years and 50 years, whereas he found that atheroma was most common after the age of 60 years I believe I happened to be one of the first to bring forward this relatively early age at which aneurysm occurs as an argument in favour of its inflammatory, not merely degenerative, origin In a short paper in 1896[3] I concluded "that aneurysm of the aorta is induced more often by the yielding of a portion of its wall affected by syphilitic or other inflammation than of a portion affected by simple atheroma", and now I feel disposed to regard aneurysm (of course excluding the rare cases due to embolism and malignant endocarditis) as *usually* the result of a specific syphilitic disease of the arterial wall

Without discussing each point separately I will state my belief that Professor Runeberg can hardly have much overestimated the influence played by syphilis in the series of cases which he investigated, that is to say, if one may read his conclusions as follows that syphilis played some part in inducing 15 per cent of the total number of deaths. It would be a very different thing to affirm that 15 per cent of the deaths were due to syphilis, for in many cases one may suppose (by analogy with one's own and other observations) that other causes have played a part as well as syphilis and that such other causes would sometimes by themselves have been sufficient to induce death, at a later period indeed, but still prematurely

Yet, though so far accepting Runeberg's conclusions, I wished to get the opportunity of comparing his figures with some obtained from an English source Such an opportunity was given me by the courtesy of Mr H. Cockburn, the manager and actuary of the life department of the North British and Mercantile Insurance Company in London The last 500 claims were examined—that is to say, a consecutive series of 500 in which a medical examination had been required on insurance, those in which the life had been accepted without special medical examination were altogether omitted Most of the 500 were males, only 45 being females The males aged 65 years or over numbered 219 and the females 21 The males who died before the age of 65 years numbered 236 and the females 24 In only three out of all the cases was a history of syphilis given and in none of these cases did the syphilis seem to have anything to do with the death All the three persons were males One died at the age of 56 years from vesical calculus, ulceration, and hæmorrhage, another died at the age of 31 years from tetanus consequent on a fracture, and the third died at 53 years of age from shock connected with an operation for appendicitis The last was a big stout man of the kind who bear operations badly, at the age of 35 years, when his life was accepted, he was six feet two inches high and weighed 18 stones

The following list, however, shows, I think conclusively, that syphilis was to some extent a cause of death in a certain number of the cases The list includes all the deaths out of the total 500 which may be regarded as throwing light on the question

No	Sex	Years of age	Cause of death
1	M	37	General paralysis
2	M	43	" "
3	M	46	General paralysis convulsions
4	M	46	General paralysis apoplexy
5	M	51	General paralysis
6	M	52	" "
7	M	52	General paralysis diarrhœa, exhaustion
8	M	53	General paralysis exhaustion
9	M	68	General paralysis
10	M	70	General paralysis exhaustion
11	M	47	Locomotor ataxy chronic cystitis
12	M	51	Tabes dorsalis (two years), ascites (four months) cardiac paralysis.
13	M	45	Cardiac and respiratory paralysis locomotor ataxy
14	M	59	Cerebral apoplexy tabes dorsalis
15	M	58	Posterior and lateral sclerosis (12 years) bedsores exhaustion
16	M	49	Ataxic paraplegia (11 months) septicæmia (four months) cardiac failure
17	F	39	Acute softening of the brain
18	M	43	Cerebral softening coma
19	M	43	" " "
20	M	44	Apoplexy
21	M	47	Apoplexy (four hours)
22	M	49	Syncope due to fatty degeneration of the hear
23	M	49	Acute dilatation of the heart.
24	M	43	Sudden death probably from the heart
25	M	49	Cardiac disease, syncope
26	M	43	Aortic regurgitation angina pectoris, syncop
27	M	50	Gout angina pectoris
28	M	50	Heart failure.
29	M	46	Thoracic aneurysm (ascending aorta)
30	M.	63	Aneurysm of aorta (six months) asthenia

I think that it is not too much to suppose that in the cas numbered 1 to 8, all cases of general paralysis in whi death occurred before the age of 55 years, syphilis had s share in the death. I would, however, omit No 9 a No 10, which, though certified as general paralysis, may account of the age have really belonged to a differe category In all the cases of tabes dorsalis (No. 11

[2] See Dr F W Mott's account of "Syphilitic Arteritis" in Allbutt's System of Medicine vol vi 1899 pp 303 et seq

[3] Syphilis and the Etiology of Atheroma, American Journal of the Medical Sciences May, 1896

No. 14) syphilis probably played a part. In the cases of other spinal affections (No. 15 and No. 16), however, there is no sufficient reason for believing that syphilis was a cause. No. 17 to No 21 are apparently all deaths under the age of 50 years from cerebral hæmorrhage or thrombosis, and (following Runeberg) I will suppose that syphilis was a factor in 75 per cent.—that is in at least three of these five cases. No 22 to No 30 are deaths from heart-stroke" at 50 years of age or under and deaths from aortic aneurysm. In one of the two cases of aneurysm, however the age was 63 years and in two of the seven heart cases the age of 50 years was already reached but in order to compare results with those of Runeberg I admit that in three cases (i.e. in half of the remaining six cases) a syphilitic infection may be presumed to have been present and to have helped to induce the early death.

According to this way of looking at the certified causes of death syphilis played a part in 18 out of 500 cases (eight cases of general paralysis four cases of tabes dorsalis, three cases of brain disease, and three cases of cardiac or aortic disease) —that is, in 3 6 per cent. I do not think that this is too large an estimate, and it is not improbable that syphilis may have had a share in a few of the other deaths—e.g in one or two supposed to be from cirrhosis or hypertrophic cirrhosis of the liver As in patients known to have been infected with syphilis the ultimate death is comparatively rarely connected in any way with the syphilis, it becomes quite clear that if death can with any probability be attributed to syphilis in 18 of the cases the disease will have occurred in a vastly greater number Yet at the medical examinations for life insurance a history of previous syphilis was forthcoming in only three of the total 500 cases However in some instances the disease may have been contracted after the date of assurance, and in some cases the applicant for insurance may have under estimated the importance of the previous venereal disease or have been really ignorant that he had had any at all Although it is probable that a history of syphilis should have been given in many more cases than it actually was the percentage of cases in which syphilis was probably partly the cause of death (3 6 per cent.) was far below that in Runeberg's series (15 0 per cent.) This may to some degree be explained by the class to which the insured persons belonged being on the average different in the two series. In conclusion I may further mention that, whereas in Runeberg's series 21 3 per cent of the deaths could be assigned to tuberculous affections, in the present series I find that in only 7 8 per cent.—that is to say in 39 cases—are tuberculous affections mentioned as having been present, and in these 39 cases three of 'fibroid phthisis are included—viz. in men aged respectively 59 61 and 63 years at death. In connexion with this relative rarity of tuberculosis it must be remembered that in 240 out of the 500 cases the age of 65 years or more was reached. Probably therefore, the series of the English insurance company represents a higher average standard in regard to chances of longevity than did Professor Runeberg's series from the Kaleva Company

FOREIGN BODIES IN THE CORNEA

By WALTER WILLIAMS, M.B.

THE extraction of small particles of iron or stone from the surface of the cornea is generally such an easy matter and, provided due precautions are taken is attended with so little reaction that it might well appear presumptuous to relate a method which I have found on occasions to be serviceable.

When the little brown or black speck is situated, as is generally the case, towards the middle of the outer aspect the enlarged pupil which follows the instillation of cocaine makes it very difficult, and often impossible, to see the offending particle. To obviate this and to secure a clear view of the object to be removed I find it useful to instil a drop of eserine sulphate (1 per cent. solution), or preferably *from* 1 *to* 2 per cent solution of pilocarpine hydrochloride, so as to neutralise the mydriatic effect of the cocaine. In this way one secures the anæsthetic effect of *the cocaine without its drawbacks* for the eserine spreading the iris as a curtain behind the dark speck renders it visible and its removal comparatively easy and that irrespectively of the direction in which *the patient is looking*

There are doubtless many in active practice who may have found some such method as I mention to be of *service*, but its usefulness has so often forced itself on my attention especially when scraping the so-called iron scale (the ferroso-ferric oxide) which follows the deposition of iron in the corneal tissue that I thought a word about it *might prove* acceptable.

THE AURICULAR REFLEX.

By E DONALDSON L.R.C P & S IREL.

SURGEON TO THE LONDONDERRY EYE, EAR, AND THROAT HOSPITAL.

I AM much indebted to Dr Walker Overend for his remarks on the above subject [1] When I published my note I regret I did not know that he had already made observations on this reflex. After reading his last communication I sent for the patient whose case is recorded[2] and whose reflex is easily obtained. I found that the middle-ear was quite dry that the polypus was gone, and that the reaction was as lively as ever A camel's hair brush thrust into the neighbourhood of the external meatus produced a forward movement of the auricle effectively quite as well, and I think better than a puff of air When testing with the air bag it is well to use a nozzle with a small bore, for in this way a sudden forcible little blast can be produced. The use of the camel's-hair brush as suggested by Dr Overend, is more convenient and better *When making* observations care should be taken that the patient does not smile or close the eyes as these movements are accompanied by upward movement of the auricle It is probable that this reflex would have been long ago noticed but that aurists when inserting the speculum insufflating powders, or applying anything to the meatus or middle-ear hold the auricle upwards and backwards to straighten the canal and by so doing often prevent this reflex movement.

PRETORIA CIVIL HOSPITAL.

A CASE OF LABOUR AT FULL TERM COMPLICATED BY PLACENTA PRÆVIA AND HYDRAMNIOS DELIVERY OF A DEAD CHILD, FOLLOWED BY PUERPERAL FEVER, TREATMENT BY ANTI STREPTOCOCCIC SERUM, RECOVERY COMPLICATED BY MALARIAL FEVER.

(Under the care of Dr HERBERT JAMES GODWIN)

THE value of anti-streptococcic serum in septicæmia is still far from being accurately determined and the question can only be decided by the careful report of cases in which the serum has been employed we are glad therefore to be able to publish the following two cases, in which the improvement that occurred appeared to be definitely due to the administration of anti-streptococcic serum. This remedial

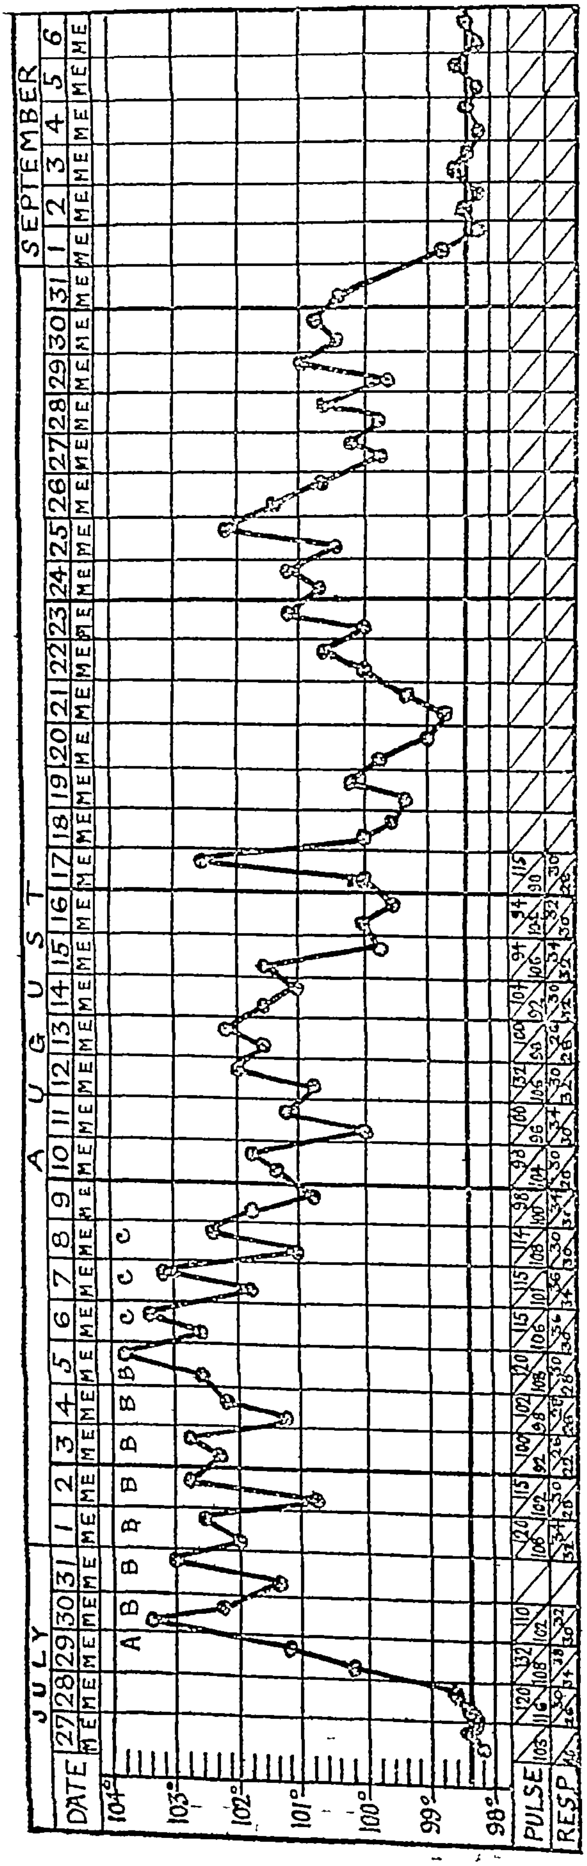
[1] THE LANCET, Sept. 6th 1902, p. 672.
[2] THE LANCET August 2nd 1902, p 606.



A 20 c.c of anti-streptococcic serum injected at 6 P.M B, 20 c.c. of anti streptococcic serum injected at 10 A.M; and 10 c.c. at 6 P.M C 20 c.c of anti-streptococcic serum injected daily

agent was first brought forward in 1895 by Marmorek who had employed it with good results in 46 cases of erysipelas Many important papers have been written on the matter At the annual meeting of the British Medical Association held at Portsmouth in 1899 Dr Herbert Spencer[1] opened a discussion on the value of the serum in puerperal fever, and the opinion he expressed was to the effect that but little was to be hoped for from its administration, and in this opinion most of those who took part in the discussion concurred. The report of a committee of the American Gynæcological Society[2] was, if anything, more unfavourable, for it concluded with the words "We find nothing in the clinical or experimental literature or in our own experience to indicate that its employment will materially improve the general results in the treatment of staphylococcus puerperal infection" The late Dr J W Washbourn[3] read at the Harveian Society of London a paper upon Treatment with the Anti-streptococcic Serum in which he spoke favourably of the serum when employed in suitable cases Dr G E Herman at a meeting of the Obstetrical Society of London on Nov 1st, 1899, related particulars of two cases in which life appeared to have been saved by the use of the serum Many other cases have been reported, with a large percentage of recoveries, but it must be recognised that recoveries are far more likely to be published than fatal cases The chief fallacies in forming a judgment on the matter are two in number In the first place sapræmia, in which only septic products have been absorbed, is very likely to have been mistaken for septicæmia and the former disease is far more likely to end spontaneously in recovery than is the latter It is therefore before all things important that bacteriological examinations of the blood should be made We would not urge that the serum should only be given when streptococci are found to be present in the blood, but for the advancement of knowledge the examinations should be made The other fallacy is that there are several varieties of streptococci and a serum prepared through the action of one form of streptococcus may prove quite unavailing against another streptococcus morphologically and tinctorially indistinguishable from the former The conclusion of the whole matter is that by a more complete examination and report of the cases in which the serum is employed is a correct estimation of the therapeutic value of anti streptococcic serum likely to be gained

A woman, aged 36 years, was admitted into the Pretoria Civil Hospital on the morning of July 27th, 1901, said to be suffering from obstructed labour and profuse hæmorrhage With regard to her past history the patient was a refugee from the North Western Transvaal and was brought to the hospital by a woman friend of hers who gave us the following history The patient was a multipara and her previous confinements were natural, she had had no miscarriages, during the first five months of the present pregnancy she was quite well, at the end of the sixth month she noticed that her abdomen was as large then as it had been in previous pregnancies at full term and that now it was nearly twice as large. At the beginning of the seventh month she began to lose blood at intervals, sometimes the floodings were profuse, at other times slight, lately they had been very frequent and at times accompanied by severe pains in the abdomen. Labour pains commenced on the 25th, two days before admission to hospital, the pains were weak and accompanied by bleeding From this date the pains continued until shortly before admission. On the night of the 26th a great deal of bleeding was said to have occurred and the pains were more severe, and as no progress was made a medical man was sent for in the early morning who after examination ordered her immediate removal to the hospital

On admission the patient was found to be a tall, dark woman Having been washed and put to bed in a private ward she presented on inspection the following appearances She looked extremely ill—the pallor of the face was death like. The mucous membranes were blanched and she had an anxious, worried expression The respirations were quick and shallow The breasts were large and full, and milk was escaping from both nipples The abdomen was very large and tense and painful on handling The lower part of the abdomen and vulva were œdematous Blood was oozing from the vagina. The feet and legs were swollen and œdematous The general condition of the patient was tremely bad, the pulse was 103, the respirations were 40 e temperature was subnormal, and the marked pallor made e wish that she had been sent to hospital earlier After a nsultation with Dr Thornton it was decided to give the tient chloroform and to empty the uterus as quickly as ssible. Having well washed the parts and given a vaginal ouche (1 in 1000 perchloride of mercury) and having taken e strictest antiseptic precautions Dr Godwin passed his and into the vagina which was very capacious the perineum aving been torn in previous labours. The os was fully ilated and nothing could be felt but a large soft mass, the lacenta. When Dr Godwin had nearly finished separating e placenta all round with his fingers the membranes rup ured and flooded the bed with an excessive amount of liquor mnii pushing his hand on up into the uterus and the lacenta to one side he felt the child's head, he then turned e child and brought down a leg delivered the child quickly, hich was dead and then the placenta, which was nearly wice the size of a normal placenta. The child a full term etus, was small and had evidently been dead several hours.

[1] Brit Med Jour vol ii 1899 p 965.
[2] American Journal of Obstetrics, Sept 1899
[3] THE LANCET, Nov 11th, 1899 p 1299

There was considerable hæmorrhage during delivery and n intra uterine douche was next given consisting of gallons f hot perchloride of mercury solution, 1 in 1000 followed by uantities of hot boric acid lotion. The patient was removed to clean bed and a pad and binder were applied. The uterus, lthough firm, did not contract like a uterus after normal abour but the hæmorrhage practically stopped after the hot ouche (and ergot given internally) The patient, although n a desperate condition, bore the operation better than was xpected 10 minims of liquor strychninæ with digitalis vere given, also brandy The pulse was very bad but mproved after injection of two pints of normal saline olution with an ounce of brandy per rectum given with a ong tube, this was repeated later The following treat nent was ordered Diet milk and beaten up eggs, raw neat juice, soda water and brandy and champagne, given frequently at regular intervals A mixture containing five grains of sulphate of quinine was administered every four hours. Hot iodine douches (one drachm of tincture of iodine to a pint of water) were given three times a day The milk was taken from the breasts and they were strapped with belladonna plaster On the evening of the 27th the patient's condition caused great anxiety and strychnine and digitalis had to be again administered There was no more hæmorrhage. The pulse was bad and the patient was very restless The temperature was normal. The bowels were opened once Later the patient became so restless and delirious that morphia had to be given. On the 28th the patient had a few hours sleep after the morphia. She was taking her nourishment well and there was no vomiting The pulse was 115. She was slightly better but complained of pain in the abdomen The urine had to be drawn off in the morning The bowels were opened once, there was no hæmorrhage The lochial discharge was scanty, there was no smell. A douche was given in the morning of tincture of iodine (one drachm to a pint of water). On the evening of the 28th when giving the douche many clots were washed out and there was a slightly offensive odour The patient still complained of pain in the abdomen she passed urine naturally and had taken nourishment well during the day She had a rigor during the night, she was very restless all night and was delirious at times On the morning of the 29th the temperature was 102 2° F, and the pulse was 120. The bowels had been opened twice. The uterus remained the same size. The lochial discharge was becoming very offensive. An iodine douche was ordered every four hours The dose of quinine was altered from five grains every four hours to 10 grains twice a day Dr Thornton, who had seen the case with Dr Godwin several times daily agreed that the uterus must have become septic and that puerperal fever was starting and that it would be best to try anti streptococcic serum at once if it could be obtained. Captain Whitstone R.A.M.C. in charge of the advanced medical store depôt, Pretoria, was able to supply plenty of serum, and Dr Godwin injected 20 cubic centimetres in the patient's flank at 6 P M During the evening the patient's temperature was 103°, the pulse was 120 and she was delirious at times and morphia was given as the patient was so restless. She slept a little during the night after half a grain of morphia and seemed a little better the next morning (the 30th). The lochial discharge was very offensive, Douches of tincture of iodine were continued four hourly The uterus was still large, there were no signs of involution The temperature was 103 2° and the pulse was 115. The tongue was dry and coated with a thick, white fur On the evening of the 30th the temperature was slightly lower The patient was still restless there was delirium at times. Some offensive clots and shreds of sloughy membrane came away in the douche in the evening The patient took her nourishment well and the pulse had slightly improved. For the following week the same routine treatment was followed but and the patient held her own. Injections of anti-streptococcic serum were given twice daily as follows: 10 A.M., 20 cubic centimetres and 6 P.M. 10 cubic centimetres. The lochial discharge was scanty and daily became less offensive. During this week the patient's general condition was often most alarming, dyspnœa, rapid pulse, faintness, and delirium were marked features and called for immediate treatment. The serum injections, which were commenced on July 29th, were continued twice daily till August 5th, after which a single injection of 20 cubic centimetres was given for the next three days. The patient by this time was daily improving and the lochial discharge was only slightly offensive. The uterus was beginning to get decidedly smaller and there had been no hæmorrhage since delivery to speak of The patient took her nourishment well which was daily increased. The temperature remained high. The pulse showed great improvement. The bowels were kept regular with small doses of calomel and great hopes were entertained of the patient recovering On August 12th, although her general condition was rapidly improving the uterus becoming smaller and the lochial discharge less offensive, douches were continued three times daily but in spite of all this the temperature still kept high. There was nothing to account for it in the chest or the abdomen as far as could be made out. Dr Godwin thought that perhaps a pelvic abscess might be present. Enteric fever being prevalent in Pretoria, Dr Godwin sent several specimens of the patient's blood to be examined, and Captain Beverage, R A M C in charge of the army bacteriological laboratory kindly examined the blood and prepared slides. He found the blood to contain the most typical specimens of the malarial parasite. From this date the dose of quinine was increased to 15 grains three times a day the diet, both solid and fluid was increased, and in spite of the temperature remaining high the patient gained flesh and strength daily The œdema of the legs had all passed away The anæmia was still very marked On August 17th she had a slight rigor followed by sweating and the quinine was increased to 20 grains three times a day The temperature did not reach normal till Sept 2nd but afterwards remained so. The quinine was stopped and a mixture of sulphate of iron was given. From Sept 2nd to 8th the patient made rapid progress and was discharged to convalesce at a friend's house in the town on the 9th The anæmia was still very marked and she continued to attend as an out patient for two months. Last Christmas Dr Godwin met her in Pretoria looking stout and well and she stated that she felt as well as ever she did in her life

Remarks by Dr GODWIN —For the kind help received in this case my sincere thanks are due to my colleague, Dr Thornton medical superintendent, Pretoria Civil Hospital also to Captain Whitstone R.A.M.C. for the supply of serum, and to Captain Beverage R.A.M.C. for several examinations of the blood and to the sister in charge of the patient, whose constant care and attention did much to save the patient's life.

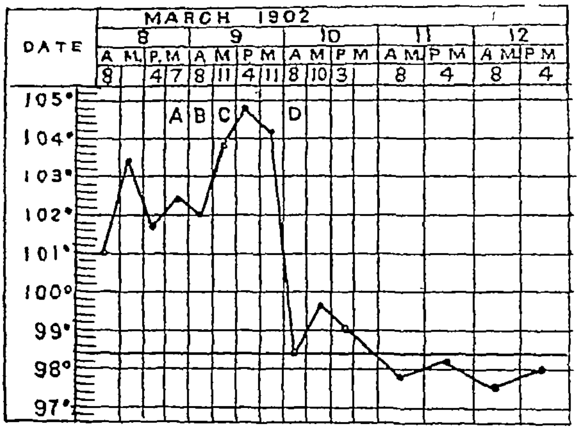
GENERAL HOSPITAL, LIPIS, PAHANG, FEDERATED MALAY STATES

A CASE OF ACUTE SEPTICÆMIA TREATED WITH ANTI STREPTOCOCCIC SERUM

(Under the care of Dr PERCY N GERRARD.)

THE following typical case of acute septicæmia treated with anti streptococcic serum deserves publication both on account of the unusually rapid improvement in the patient's symptoms and also on account of the time which had elapsed since the preparation of the serum

The patient was a Chinaman aged 27 years, and was admitted to the General Hospital Lipis, Pahang on March 7th 1902, suffering from debility and inanition. He was in a miserable condition but no organic disease existed at the time of his admission. The day after his admission his temperature rose to 103° F in the afternoon and he complained of pain in the left temple and posterior auricular region Early on the morning of the 9th a hard swelling accompanied by an erysipelatous blush was noticed involving the left side of the face so as to cause puffing of the eyelids and cheek of that side At 7 30 A.M he had a severe rigor lasting about half an hour Owing to deep tension the inflamed area was incised and about half an ounce of pus was evacuated. This operation was performed at 8 A.M His temperature continuing to rise from 102° to 103° at 11 A.M. and his general condition becoming so grave as to necessitate prompt measures if his life was to be saved led Dr Gerrard to decide upon what he considered the forlorn hope of injecting old anti streptococcic serum, and this operation was accordingly done at 11.30 A M, the patient being in a semiconscious condition, his pulse was 109 per minute and thready, and his temperature was 104° During the forenoon and afternoon no improvement evidenced itself and on seeing the man late the same evening Dr Gerrard considered him to be practically moribund. Towards midnight the temperature, which touched an acme of 104 8° at 4 P M, began to show slight signs of abating and at 7 A.M on March 10th it reached 101° To Dr Gerrard's surprise on visiting the ward about 10 A.M on the morning of the 10th his temperature was normal, the erysipelas was fading, and his general condition was much improved.



A, Rigor B, Incision of abscess C, Serum injected. D, Counter-opening made

The subsequent history of the case needs no comment. Dr Gerrard was called away from the station in the afternoon of the 10th and the following extract from a letter of his chief dresser (Mr Philips) will suffice to complete the history of this interesting case "I have pleasure in informing you that satisfactory results have been obtained with the injection of anti streptococcic serum. The patient is now quite recovered. There is no further fever The abscess is almost healed He eats and sleeps well. No medicine whatever has been administered throughout except whisky as a stimulant. He is now walking about the ward."

Remarks by Dr GERRARD —In concluding the history of this case I would lay special stress upon the age of the serum which had been in my possession for over two years in the Malay States without any preservative precautions other than its being kept in the dark. This shows that in case of need even an old serum may be serviceable. What was used on this occasion was the desiccated serum prepared at the Pasteur Institute, Paris, and recently boiled water was the vehicle

Reviews and Notices of Books.

Studies in Physiological Chemistry Edited by R. H CHITTENDEN, Ph.D New York Charles Scribner's Sons London Edward Arnold. 1901 Pp 424 Price 17s

THIS volume contains the results of the more important studies relating to the work of investigation carried out in the laboratory of physiological chemistry of the Sheffield Scientific School of Yale University during the years 1897-1900 The work contributed by the students in this laboratory continues to be of a most excellent and valuable description The editor himself contributes in collaboration some important papers That on the Influence of Borax and Boric Acid upon Nutrition, with Special Reference to Proteid Metabolism, is, in particular, *apropos* at the present time Professor Chittenden and his colleague Professor William J Gies find that moderate doses of borax up to five grammes per day, even when continued for some time, are without influence upon proteid metabolism. Large doses have a direct stimulating effect and tend to retard assimilation Boric acid is practically without influence upon proteid metabolism Both borax and boric acid are quickly eliminated in the urine, but neither has any influence upon the putrefactive processes of the intestine A paper on the Chemical Composition and Nutritive Value of Some Edible American Fungi is contributed by Professor Lafayette B Mendel. In this he concludes that the fungi form no exception to the ordinary classes of fresh vegetable foods and, indeed, that they take a decidedly inferior rank in comparison with many Thus the expression "vegetable beef-steak," he writes, "would seem to be scarcely appropriate when applied to mushrooms in a strictly chemical sense." In another interesting paper Professor R. H. Chittenden and Mr A. N Richards discuss the variations in the amylolytic power and chemical composition of human saliva. They find that mixed saliva contains normally no sodium carbonate whatever, the alkalinity shown by litmus being due to alkaline phosphates The alkalinity is greater before breakfast than after the morning meal—a conclusion which stands in direct opposition to the statement that the alkalinity is least when fasting Mechanical stimulation, as when chewing a tasteless substance, and alcohol taken into the mouth, lead to the outpouring of a secretion richer in alkaline reacting salts and in amylolytic power than the secretion coming without stimulation. We suggest that it would have been interesting to determine what influence smoking has upon the saliva. In another paper, on the Occurrence of Iodine in the Thymus and Thyroid Glands, Professor Mendel concludes that the accessory thyroids in man may contain both relatively and absolutely more iodine than the thyroid proper of the same individual. He confirms the observations that the thyroids of newly born children contain no iodine, while he failed to obtain any satisfactory evidence to show that the carefully isolated thymus of man or animals contains iodine Altogether, this volume presents an interesting series of physiological studies

The Theory and Practice of Medicine By HENRY WALTER SYERS, M A, M.D Cantab, &c, Senior Physician to Out-patients to the Great Northern Hospital In two vols Vol II London Rebman, Limited 1902. Pp 480 Price 10s net (Vols I. and II., 25s)

IN reviewing the first volume of this work we were unable to speak favourably of it, nor is our opinion altered by a perusal of the second volume now before us Most of the diseases are so briefly and scantily discussed that very little information is conveyed to the reader There are, however, a few exceptions The remarks on Pernicious Anæmia are distinctly good, and had all the sections in the two volumes maintained the same standard we should have been able to speak far more highly of the work The consideration of Diabetes, on the other hand, is dismissed in five and a half pages, only about three quarters of a page being devoted to the treatment of the disease The modern method of allowing patients to partake of a certain amount of carbohydrate food is not even mentioned The etiology and morbid anatomy are disposed of in one page and yet the title of the work is "The *Theory* and *Practice* of Medicine."

Dr Syers is certainly at his best when giving an account of symptoms, and some of the diseases of the nervous system are well and accurately described His remarks on Tuberculous Meningitis, General Paralysis of the Insane and Locomotor Ataxy certainly convey a good deal of information. He has made an error, however in not dwelling more strongly on differential diagnosis

A work of reference on practical medicine to be of value to the practitioner must contain suggestions which will assist him in cases of doubtful diagnosis, but each section in Dr Syers s book contains only three divisions (with headings in the margins)—namely Symptoms" 'Causation and Morbid Anatomy and "Treatment" As we have already hinted, the description of the symptoms is usually good, but the other divisions are greatly wanting in detail and in the discussion of the most modern views and methods.

Some Apostles of Physiology By WILLIAM STIRLING M.D Edin. D Sc. Brackenbury Professor of Physiology and Histology, Owens College. 1902. Privately printed by Waterlow and Sons, Limited London

THIS beautiful volume is dedicated to Mr Walter Whitehead, 'whose love of art and whose liberality have made it possible to issue this volume in a manner worthy of the event it is designed to celebrate. The event is the 1902 Manchester meeting of the British Medical Association and author and patron have indeed united to produce a work at once creditable to themselves and a *κτημα ες αει* for those who are fortunate enough to possess a copy Professor Stirling tells us that in his Lectures on Physiology he has been in the habit of giving a short sketch of the lives and of showing the printed works of illustrious "Apostles" and of their colleagues and the present work is founded on these notes Although a few earlier observers are mentioned the book practically begins with an account of the great Vesalius. After him comes the great Servetus, hat pathetic figure in the history of medicine and theology All the world knows how Servetus the heretic was burned by Calvin the schismatic, and with him nearly every extant copy of the 'Christianismi Restitutio in which to quote Professor Stirling he showed that he had grasped the true features of the pulmonary circuit.

Of the great Haller Professor Stirling says His knowedge was encyclopædic his tastes catholic, his aspirations poetical, and he was supremely devout withal." Haller was one of the many interesting people with whom that prince of adventurers, Jacques Casanova, foregathered and his account of his interview with Haller may fitly be referred to here 'Monsieur Haller was some six feet in height, big in proportion, and handsome, in fact, he was a kind of Colossus, both physically and mentally He received me with politeness and when he had read the letter of Monsieur De Muralt he was still more affable, a fact which showed me that a good recommendation is never out of the way The great *savant* opened to me the treasure house of his knowledge, answering all my questions with precision and with a modesty which sometimes appeared to me overdone for t the same time that he expounded to me the most ut-of the-way subjects he did so with an air of a student who seeks instruction. Haller was a great physiologist, a great physician and a great anatomist. He called Morgagni his master During my stay with him he showed me a quantity of letters from Morgagni and from Pontedera a professor of botany a science in which Haller excelled o a great degree. Haller was a *savant* of the first rder but he never posed as such for the sake of showing ff, neither in his family circle, nor when he found imself in the society of people who for the sake of musing themselves wished to talk science. Nobody knew etter than he how to bring himself down to any other erson s level. He was pleasant in all kinds of society and rarely displeased anybody In what consisted this quality of being universally agreeable I cannot tell and it would be easier to give a catalogue of those qualities which he had not than of those which he had. He had neither haughtiness nor vanity nor a tone of superiority in fact none of those faults with which those who are called learned and witty are often rightly reproached. He talked well, always said something worth listening to, and never monopolised the conversation

As Casanova, although a scoundrel was a very shrewd judge of character, the above remarks show that Haller was no ordinary man. So the tale of intellect goes on through Hunter and Lavoisier Bichat and Bell, Ludwig and Pasteur down to Sharpey Waller and to Huxley as a finish— for 'the present," says Professor Stirling—of the story of Some Apostles of Physiology" The illustrations, the majority of which are collotypes, are most beautifully executed and reproduced and the whole work is highly creditable to everyone concerned.

LIBRARY TABLE.

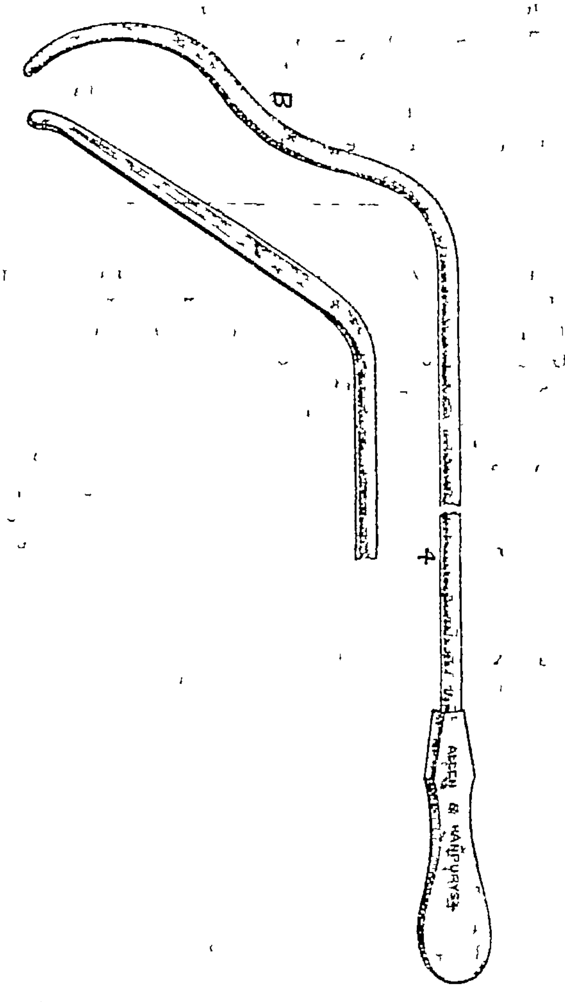
Atlas and Epitome of Otology By GUSTAV BRÜHL, M.D Berlin, with the collaboration of Professor Dr A. POLITZER of Vienna. Authorised translation from the German, edited by S. MACCUEN SMITH M.D Clinical Professor of Otology Jefferson Medical College, Philadelphia and Otologist and Laryngologist to the Germantown Hospital, Philadelphia. With 244 coloured figures and 39 lithographic plates and 99 text illustrations Philadelphia and London W B Saunders and Co. 1902. Pp 292 Price 13s net.—A review of this work in its original edition has already appeared in our columns in which we spoke very favourably of it. The coloured illustrations are, as we said, excellent, a very large number of them being from preparations in the possession of Professor Politzer while in the text his master hand is amply evidenced. The translator has, he tells us, not adhered rigidly to the original text, but has endeavoured to express the author's ideas correctly and where necessary has made certain additions In the chapter on Examination of Patients this free translation falls in with what we said with regard to the almost too terse and condensed chara er of the original text thus making the book more easy to read and also more easy to digest. Certainly such a work as this in the English language has long been wanted Dr MacCuen Smith has succeeded admirably in his task and his translation will be welcomed by students of otology who are not conversant with the German language. Considering the small size of the book the amount of information which it contains is enormous The only portions of the book which do not perhaps quite express the current opinions in England are those which deal with the major operative proceedings on the mastoid process, all mention of the use of large grafts according to Ballance s method being ignored and intracranial complications are evidently considered to come more into the province of the general surgeon, the symptoms of cerebral abscess being rendered in an extremely condensed form even in the translation. As a handbook of otology we do not think that there is a better one of its size in the English language, it will be of great assistance to senior students and will be welcomed by all post-graduate teachers for the use of their classes.

DONATIONS AND BEQUESTS —Under the will of Mr H. W Watts of Highbury the Great Northern Central Hospital receives £200 the London Fever Hospital Hospital for Di eases of the Chest, Islington, the Royal Hospital £100 each the Royal City road and the London Hospital and the Islington Dispensary and the Free Hospital, £200 Holloway Dispensary £50 each.

New Inventions.

A NEW SOUND AND A URETHRAL STAFF

THE instruments here illustrated I have found to possess definite usefulness The instrument marked 4 shown with its handle I intend chiefly for cases where it is desirous to bring the vesiculæ seminales, the base of the bladder, and the prostate more satisfactorily within reach of the finger, placed in the rectum for purposes of examination usually, but sometimes for operative procedure. Personally, I never, without its use, satisfied myself that I could feel the normal vesicles The instrument being passed, the prostate fits into the space B, and this gland, together with the parts named, is easily forced down by gentle properly directed pressure towards the finger, and at other times towards the perineum if desired The staff, of which the beak only is shown, is intended chiefly for purposes of fixation and approximation in abscess in and about the prostate whilst incisions are made. By its aid however, I have treated two cases of annular stricture in a way which, I think, is quite novel I introduced the tapered beak through the strictures and cut from the outside nearly down to, but not through, the mucous membrane The strictures were then continuously dilated from within without rupture of this membrane—a very desirable thing when possible.



The instruments were made, from models shown to them, by Messrs Allen and Hanburys, Plough court, Lombard-street, London E C.

A SANATORIUM FOR PULMONARY TUBERCULOSIS —The subscriptions to the Didworthy Sanatorium for Consumption for the counties of Devon and Cornwall are steadily increasing, upwards of £5000 having now been received towards the £6000 required to commence the scheme.

THE WATER-SUPPLY OF LISBON

IN past years the city of Lisbon must have suffered considerably from want of water During the earlier part of the eighteenth century it is estimated that the supply amounted to no more than seven litres per head.[1] About the middle of that century (1748) some fresh sources were tapped and the quantity per individual was raised to 8·4 litres In 1835 an aqueduct was completed which served, by bringing in a new supply, to raise the amount per head to 14·3 litres From this date nothing very much was done (except the utilisation of some ancient sources in 1869) until 1880, when for the first time water was brought from Alviella, a place situated at a distance of about 100 kilometres from Lisbon

On the introduction of these new supplies those already in use were not abandoned, and at the present time water is obtained from three distinct sources, about which a few words may be said 1. The low waters are derived in the neighbourhood of the city from the southern slope of the hill of St. Jorge This is the water which has been longest in use It is not only liable to pollution but is undoubtedly polluted, as shown by the fact that the bacillus coli has been frequently found in it No method of purification is adopted in the case either of this or any of the other water which is distributed in Oporto 2 The high waters are derived from a large number of separate sources, 58 in all, which are situated at a distance of 12 or 13 kilometres from the city, to which the water is conducted by the aqueduct of D João V The sources of this water do not all appear to be above suspicion. Some are near houses and some are near ponds used by laundresses These supplies cannot be considered altogether free from the possibility of contamination. They ought to be, and, in fact, are, it is said, the objects of special "surveillance" "Field observation" as to the probability of contamination does not satisfy the writer of the water company's report, he awaits with more confidence the results of bacteriological examination 3 The water of Alviella, the latest of the supplies obtained, is the most ample in quantity and the best (or least bad) in quality It is true that the bacillus coli has been found in specimens of it which were taken in Lisbon, but the pollution has apparently been traced to a source which affected the water *en route* The spring itself seems to be free from suspicion as it is derived on high ground from "vast subterranean reservoirs and calcareous caverns," whence it is conducted through an aqueduct to the city

The manner of distribution is so arranged that the water derived from each of these three sources has its own area of supply About 25 per cent. of the water is distributed by gravity and 75 per cent is pumped up to the reservoirs, of which there are 11 It is arranged that in case of emergency each of the three systems can be utilised to aid either of the others The supply is in the hands of a company which is required to supply gratuitously to the municipality all the water required for public purposes The quantity of water which is required for municipal purposes is considerable, it always greatly exceeds the amount used by private consumers The income of the company is derived from payments made by private consumers and by the Government.

The private supplies are given by metre—the method favoured by some authorities in the City of London Many varieties of gauges are in use and amongst these may be mentioned the "positive" instruments of Pinto Bastos, Frost-Tavenet, Frager, Kent and Worthington, and the "inferential" metres of Tylor and of Siemens and Halske. Lisbon therefore offers a fine field to those who wish to observe the practical working of metres and the advantages or disadvantages attending this method of supply Those of our countrymen, however, who may have occasion to go to Lisbon will do well to eschew rather than to swallow the water of that city

The Compagnie des Eaux de Lisbonne may be congratulated on having produced an excellent pamphlet which gives a full account of the water supply of the city The volume contains good illustrations of the aqueduct of the high waters of the Alviella Springs, and of various parts of the aqueduct, the arcades of Lounceira and of Pero Filho, of the siphon in the Valle de Torno, and of the bridge siphon at

Sacavem. There are pictures also of things of less interest, of boilers, of an engine-room and of a reservoir under construction. Excellent maps show the course of the aqueducts and the distribution of the water service in the City of Lisbon and coloured charts graphically illustrate the amount of water derived from each of the different sources, and the amount used respectively by the Government by the municipality and by private consumers.

VENEREAL DISEASE IN PRUSSIA.

AN inquiry into the prevalence and distribution of venereal diseases amongst the inhabitants of Prussia has recently been carried out under the auspices of the Minister who is charged with the supervision of medical affairs in that country Early in March, 1900 the whole of the medical men engaged in the active exercise of their profession within the limits of the kingdom were called on by the authorities of the various medical associations (*Ärztekammer*) to complete returns showing the number of adult patients who on a given day were under their professional care for venereal affections of every description. The number of practitioners exclusive of medical officers of the army and navy to whom circulars were issued was 14,000 but no more than 9204 replies were received upwards of a third of the recipients having apparently declined to respond.

From the completed returns which have been collated by Professor A. Guttstadt[1] it would seem that on April 30th 1900 the day on which the enumeration took place no fewer than 40 902 adults were under treatment privately in Prussia on account of venereal disease in some shape or form other than hereditary 30 383 individuals being males and 10 519 females. The distribution of the cases according to sex and centrés of population is well shown in the subjoined table —

Males

—	Population of Prussia (adults) Jan 21st 1900		Cases of venereal disease treated privately on April 30th 1900.	
	Number	Percentage.	Number	Percentage.
(a) Berlin	600,907	5·68	8,629	28·07
(b) 17 towns of 100 000 inhabitants and upwards..	1,012,822	9·40	10,116	33·29
(c) 42 towns of from 30 000 to 100 000 inhabitants	702,249	6·62	4 101	12·50
(d) 47 towns of less than 30 000 inhabitants ..	245 933	2·28	1 103	3·65
(e) Total for the 107 towns	2,561,911	23·78	23,854	78·51
(f) Villages and rural districts ..	8,212 964	76·22	6,529	21 49
(g) Total males	10 774 875	100·00	30,383	100·00
Females.				
(a) Berlin...	671,070	5·90	3,069	29·17
(b) 17 towns of 100 000 inhabitants and upwards	1,194 000	10·49	3,330	31·66
(c) 42 towns of from 30 000 to 100 000 inhabitants	789 462	6·76	1,354	12·87
(d) 47 towns of less than 30 000 inhabitants. ..	270,684	2·33	457	4 35
(e) Total for the 107 towns..	2,905 186	25·53	8,210	78·05
(f) Villages and rural districts ..	8 475,461	74·47	2,309	21·95
(g) Total females	11,380 657	100·00	10,519	100·00

It is clear from the foregoing table that venereal affections in Prussia are enormously more prevalent amongst dwellers in crowded centres than in the sparsely peopled country In 107 towns with an aggregate population of 5 467 107 adults of both sexes there were 23,854 males and 8210 females under treatment privately on the day the census was taken, whereas in the rural districts, containing 16 688 425 inhabitants, the corresponding numbers were for men 6529 and for women 2369 That more males than females were affected is also shown, but the disproportion is believed to be considerably less than would appear from the returns In the first place, women are said to be able to procure for themselves clandestine treatment, and secondly they are far more prone than men to the concealment of their disease. However this may be it is certain that if hospital patients had been included in the inquiry the discrepancy between the sexes would have undergone sensible diminution During the year 1899 14 405 women chiefly prostitutes, were treated for venereal disease in the public hospitals, while the number of male cases for the same period was 15,181. In this connexion the remarkable fact stands out that on one single day the persons under the care of qualified medical men as private patients exceeded by more than a fourth the contingent treated during an entire year in the hospitals

The diseases reported by the 9204 private practitioners have been classified as shown in the following table —

—	Number			Percentage.			Per 10 000 adults		
	Males.	Females.	Total	Males	Females	Total.	Males.	Females.	Total
Blennorrhagia	16 676	5,295	21,971	54 89	50·34	53·72	15·43	4·65	9·92
Soft chancre	2,103	277	2,380	6·92	2·63	5·82	1·95	0·24	1·07
Syphilis primary and secondary	8,112	3,188	11 300	26·70	30·31	27 63	7·53	2·80	5·10
Tertiary syphilis	3 492	1 759	5 251	11·49	16·72	12·83	3·24	1 56	2 37
Total	30,383	10,519	40,902	100·00	100·00	100·00	28 20	9·24	18·46

Three fifths of the diseases were returned under the first two heads but the others indicate a sufficiently serious state of affairs more especially when it is considered that nearly a third of the syphilis was classed as tertiary

In the army the inquiry seems to have been restricted to a body of troops numbering 460,000 men. Amongst these, on April 30th 1900 there were 444 cases of blennorrhagia, 74 of soft chancre, 174 of primary and secondary syphilis and seven of tertiary syphilis. The total 699 gives a rate of 15 20 per 10,000 of strength and compares very favourably with the corresponding totals in civil life. In Berlin the rate per 10 000 adult males was 141 94 in 17 town with more than 100 000 inhabitants it was 99 88 in 42 towns with from 30 000 to 100 000 inhabitants 58 40 in 47 towns with less than 30 000 inhabitants 45 06 and for the whole kingdom, 28 20.

In Prussia there are provident societies having an aggregate membership of more than 4 000 000 but until recently no member disabled through venereal disease was allowed to draw the indemnity which is granted for ordinary affections In April 1892, the Government made it possible for this to be done but the whole of the societies have not as yet availed themselves of the permission In 1899 only about a third of the venereal patients who had been treated in the hospitals were allowed their expenses

In order to combat the spreading pestilence a number of prophylactic measures have been devised amongst them being (1) an improved system for teaching venereology" in the medical schools (2) free post-graduate instruction by salaried professors (3) enlightenment of the public regarding the gravity of the question by means of pamphlets and leaflets in collaboration with the Order of Good Templars,[2] the fact that continence is far from exercising an injurious influence upon physical and intellectual development being especially impressed upon the youth of both sexes (4) special provisions for the guidance of medical officers attached to the sanitary police in town and country (5) a scheme to ensure the instruction of midwives regarding venereal diseases—their clinical characteristics and modes of dissemination. Finally the surveillance and regulation of prostitution have received renewed attention with a view to the suppression so far as possible of clandestine prostitutes.

THE LANCET.

LONDON SATURDAY, SEPTEMBER 27, 1902

Small-pox in Lambeth in 1901-2

VARIOUS questions of interest are referred to in a report just issued by the medical officer of health of Lambeth, Dr JOSEPH PRIESTLEY, on the prevalence of small pox in that borough during the recent epidemic in London.

The statistics of the report furnish the usual evidence of the power of vaccination and revaccination to control small pox. In children under 10 years old it is estimated that the proportion of unvaccinated to vaccinated persons in Lambeth was as one to five. The vaccinated five sixths furnished 11 cases of small pox and the unvaccinated sixth furnished 39 cases If the vaccinated children had contributed to the prevalence of small-pox in the same proportion as the unvaccinated they would have yielded not 11 cases but 195 As regards fatal small-pox, the vaccinated five sixths under 10 years old had among them one case, while the unvaccinated sixth had nine cases, of which four were under a year old Over 10 years of age, owing to partial wearing out of protective power, the differences between vaccinated and unvaccinated are not so striking, especially as to attack rates, though as concerns fatality rates there is still abundant evidence of the virtue of vaccination, the deaths being only 37 instead of 204

It is a favourite sophistry of opponents of vaccination that statistics and observations supporting the value of the Jennerian prophylactic are untrustworthy because of the bias of the observer or reporter There are circumstances, however, in which no such bias can have any scope, and an example of this is provided in the statistics of "quarantine" contacts in Lambeth These people were under observation as to their vaccinal condition before ever small-pox had appeared on them, and when it was impossible to know who among them were in the incubation stage of the disease and who were not. Among 3876 adult contacts who had been vaccinated or revaccinated 103 developed small pox, whilst among 37 unvaccinated 12 developed small pox—one case in 37 among the former and one in three among the latter Of contacts under 10 years old there were 935 vaccinated or revaccinated, and six of these, or one in 133, took small pox , whilst among 73 unvaccinated, 18, or one in four, were attacked Among 133 visitors to the small-pox hospitals only one caught small pox and he was a "conscientious objector" who had refused revaccination.

To prevent so far as possible mistaken diagnosis between chicken pox, lichen, and other diseases, and small pox, Dr PRIESTLEY issued a circular to medical men in Lambeth offering to consult with them in doubtful cases As a result 277 cases were intimated, of which 94 were small-pox, 84 chicken-pox, 17 lichen, 15 erythema, 19 acne and ecthyma, and so forth These consultations were obviously most useful, but Dr PRIESTLEY'S speculation as to what might have happened had all the 94 small pox patients been treated at home seems unnecessary, as it is inconceivable that this uniformity of error would have occurred in any circumstances The Order of the London County Council making chicken pox notifiable in London came into force on Feb 7th of the present year and by the end of August 988 cases had been notified in Lambeth Of these only four proved to be small pox, and it is pointed out that the four would have been heard of through the system of voluntary notification, so that Dr PRIESTLEY holds compulsory notification of chicken pox to have been practically useless in Lambeth In other places, however, where, perhaps owing to the medical officer of health being in general practice or to the existence of less friendly professional relations than fortunately seem to exist in Lambeth, compulsory notification of chicken pox in presence of the prevalence of small pox may be by no means useless

"Quarantining" was resorted to very extensively in Lambeth and with very good results The term, as used in the report, appears practically to mean that contacts were kept under observation at their own homes for a period of 16 days after exposure to infection. A special building was regarded as unnecessary, except for a few hours during disinfection of dwelling and clothing, and there was no hindrance to the "quarantined" going about. There appears to have been some restriction to their going to work, as it was only under conditions satisfactory to the health officer that certain of them were allowed to do so The report does not discuss or explain the differences between the risks of going to work and of going about the streets, or the system upon which the one was sanctioned and the other hindered. The total number of persons kept under observation was 5087, and of these 137 (or 141) developed small pox and were removed to hospital, with the very satisfactory result that no single further case followed from any one of them.

The problem of the prevention of small pox epidemics and of the value of measures such as quarantine and isolation must continually vary as between one place and another and between one time and another, according to the vaccinal condition of the threatened population. If the whole of London or of Lambeth were unprotected against small-pox, quarantine and isolation would be, of course, impracticable In Lambeth, we are glad to learn from Dr PRIESTLEY'S report, conscientious objectors are almost non existent, but in the years 1893-97 the official returns show that the children "unaccounted for" averaged nearly 25 per cent. Among the 5000 contacts kept under observation any such percentage was greatly reduced immediate vaccination, and under these circumstances disease was held in check to the degree recorded Dr PRIESTLEY If vaccination and revaccination w to fall into abeyance the uphill battle which was so fought this time against small pox in Lambeth would s other time become a downhill *débâcle*, notwithstand quarantine and isolation and disinfection. If, on the other hand, vaccination and revaccination were to become universal there would be no epidemics of small pox involving all the elaborate and expensive measures of control which have to be adopted in this country in the present day, the worries and difficulties and disputes about sites and sizes of small pox hospitals would vanish and there would be no necessity in Lambeth or elsewhere for consultations regarding hundreds of doubtful cases or for quarantining" thousands of contacts or for disinfecting tens of thousands of articles of bedding and clothing Once in a while a case might indeed occur as in Germany but epidemics, with all their labours and anxieties and outlays and their toll of disfiguration and death would be matters of history The nearer we approach to universality of vaccination and revaccination the nearer shall we be to reaching this goal, the farther we depart from it, though hospitals be multiplied all over the country the more hopeless will it become to cope successfully with small pox epidemics We trust, therefore that Dr Priestley's fear that public apathy regarding vaccination will result in its further neglect, so that Lambeth and other places will be able to depend on it even less in the future than in last year's epidemic, may prove to be unjustified and we hope that the Government next year will be found alive to its duty in the matter of legislation with regard to vaccination so that not merely the protection of infants but of adults, will become a matter of national concern and the various defects of detail which have been discovered in the course of the legislative experiment begun in 1898 will be remedied in which case the country will obtain the full benefit of the experience which has now been gained alike of the strong points and the weak of the existing vaccination laws.

◆

Methods of Intestinal Anastomosis

THE question of the treatment of a wound of the intestine must have presented itself to the notice of members of the healing art from the earliest times, for even palæolithic implements were fully capable of inflicting such injuries. Doubtlessly from time to time attempts were made to bring together the divided edges with more or less success but it is certain that the failures must have far exceeded in number the successes for sepsis was almost inevitable under the conditions then obtaining The earliest description of intestinal suture that we possess is found in a somewhat obscure passage in a Sanscrit Veda. Celsus advised the use of sutures for wounds of the large intestine but says nothing as to the method employed. Galen was in favour of suturing the stomach and the large intestine but he tells us that if the small intestine is sutured recovery rarely follows. The Arabian physician Abulcasis, recommended suture of a wounded bowel and advised the employment of catgut. Roger of Parma and Roland in the thirteenth century made use of a little elderwood tube which was placed in the bowel and the edges of the wound were united with silk In the succeeding centuries many writers on surgery advocated intestinal suture and they described many different methods gradually drawing near to those employed at present. If suture of the bowel is important for wounds it is still more important in cases in which excision of a portion of bowel is necessary for gangrene or new growth Reybard in 1833 first attempted to excise a complete segment of intestine he removed three inches of the colon united the divided ends by sutures, and the patient recovered Three years later Dieffenbach operated on a case of strangulated hernia he found the bowel gangrenous and having excised the necrosed portion he sutured the ends together in this case also recovery followed.

It is clear, then that for many centuries the question as to what is the best method of uniting two portions of bowel, and of closing a wound or rupture of the intestine has been considered and discussed. The question appears to be simple and it might be thought that in the many years which have elapsed since it was first propounded surgeons would have become fully agreed on the answer, yet we must confess that it is not so and the reason for this want of unanimity is to be found in the fact that the question is by no means so simple as it may appear at first sight The introduction of antiseptic and aseptic surgery has cleared away one great obstacle to intestinal surgery The older surgeons were hampered by sepsis and their most earnest endeavours could only occasionally succeed. So far the problem has been simplified but it is still difficult Before any method of suture can be characterised as perfect it must fulfil many diverse requirements. It must be simple in principle easy in application and rapid in use. Moreover it must approximate the several layers of one piece of bowel to the corresponding layers of the other thus, the mucous membrane must join the mucous membrane, the muscular layer must become continuous with the muscular layer and the peritoneum with the peritoneum. The method must not tend to produce any noticeable narrowing of the gut. What method can fulfil all these requirements? There has been no lack of ingenuity in devising new procedures, for up to the present more than 200 methods have been described. It is difficult to realise that it is possible that there should be so many different ways of joining two pieces of intestine, but in many cases old methods have been re-invented and this is true of some very recent devices. Practically the methods may be divided into those employing some form of mechanism and those which make use of no such adjuvants.

Mechanical aids for intestinal anastomosis have been very numerous. We have already referred to the elder wood tube which was employed 600 years ago by surgeons of the school of Salerno and this is the type of many others. Senn's plates Mayo Robson's bone bobbins Paul's tubes *et hoc genus omne* have been invented and employed In some cases they have been composed of a digestible material so that the digestive juices may be able more or less to destroy them when they have accomplished their function, in other cases they are intended to be removed immediately before the bowel is sutured in others again, they are left to be carried away with the fæcal masses. This form of apparatus has culminated in Murphy's button, which is a marvel of ingenuity It undoubtedly affords in skilled hands an extremely rapid method of joining two pieces of bowel and numerous favourable results of its employment have been recorded, but in hands unfamiliar with its employment the button may readily prove useless, moreover, it is not rarely badly made, with the spring too hard or too soft, and its weight tends to drag down the piece of bowel in which it is placed. That it is sometimes or even frequently retained within the bowel for long periods is also an argument against its employment. Yet in spite of its disadvantages, which are many, it will probably remain for years one of the most rapid methods of intestinal anastomosis The absorbable mechanical supports such as the "bobbins" and "tubes" are certainly of great value and assist the operator enormously in suturing the intestine, but they are frequently not available when they are required LAPLACE'S ingenious forceps deserves mention, but it has been adopted to only a very small extent

If any method can be devised which is rapid and safe and yet dispenses with any mechanical appliance it will surely prove a definite advance in intestinal surgery Simple drawing together of the edges by LEMBERT or CZERNY LEMBERT sutures is preferred by many surgeons, for nothing more is required than a needle and silk, but except in very practised hands the process is certainly tedious, and in this operation time is often of the first importance. In 1892 MAUNSELL introduced a very rapid method of intestinal anastomosis It consists in bringing out both the ends of the bowel through a separate longitudinal slit in the wall of one portion of the intestine Sutures are passed through all the coats of the bowel, which is then returned, and the longitudinal incision is closed. The method is speedy, but it has not been very widely adopted, for it has been felt that it is undesirable to make a fresh incision if it can be avoided At the present time it may be said that probably the majority of surgeons employ simple suturing The latest contribution to the subject is by Dr F H. WIGGIN of New York in a paper read before the New York Academy of Medicine in March of this year His method is essentially a modification of MAUNSELL'S, resembling that method in the sutures being inserted through the whole thickness of the bowel, but omitting the fresh longitudinal incision through the intestinal wall. The operation is as follows the two ends of the bowel are united by means of two sutures passed through all the coats, one suture being placed at the mesenteric border and including a portion of the mesentery on both sides, and the other being situated immediately opposite to the first By means of these two sutures the bowel is held in position while the other sutures are being inserted. These sutures are passed through all the walls of the bowel and the knots are left in the cavity of the gut This suturing is continued until only one suture remains to be placed and at this spot a LEMBERT stitch is employed If the sutures have been correctly placed about one-eighth of an inch apart and at the same distance from the edge of the bowel the peritoneum will have been turned in and no stitches will be visible except the last. Slight modifications of the procedure enable two portions of bowel of unequal size to be united It is, of course, early yet to say what will be the fate of this operation, but it appears to include all the merits of MAUNSELL'S operation without its chief disadvantage and deserves, and will doubtlessly receive, the due consideration of surgeons

Some Lessons of the Late War

THE war in South Africa having terminated it will before long possibly possess as little interest, as far as the general public is concerned, as a last year's almanack. If the announcements are to be relied upon, however, that General DE WET has been occupied in writing a book about it, that ex President KRUGER has been preparing another on the same subject and on the causes which led up to it, and that in addition an official Boer record of the war is to make its appearance we are not yet likely to lose sight of the subject altogether Before it reaches a stage when time's obliterating sponge is applied to it and public attention is solely directed to the settlement of the newly acquired country there are a few facts and considerations which seem to be worthy of being recorded

In the first place the view that the losses in modern warfare would be enormously increased—with a correspondingly large increase, of course, of medical aid of all kinds—owing to the improved weapons employed, has not been borne out by the experience obtained in South Africa. But it must be remembered that the conditions in that country were altogether exceptional However sound theoretically may be the reasoning about the range, rapidity, and accuracy of modern firearms as applied to ordinary European warfare, its deductions are practically inapplicable in the case of the tactics employed by the Boers operating in a country which is, topographically speaking, so eminently suited to defensive warfare Their object was always to conceal themselves and to refuse to be drawn, never to show themselves in the open unless it suited their purpose to do so, and always to reserve their fire until an attacking force reached a given point where previous experience had shown that they could be hit with an almost automatic certainty This is what actually happened in the fighting in Natal until the British, having learnt the lesson of a dearly bought experience, altered their system It is doubtful whether the lessons of the war are altogether applicable to European conditions, but it is certain, if we judge from the late foreign military manœuvres, that continental armies in fighting with the Boers would have fared no better than, if as well as, we did Taken as a whole, the British losses in killed and wounded during the late war were relatively small as compared with some of those in WELLINGTON'S campaigns or with the losses in the Franco-Prussian and other wars The deaths from disease and the inefficiency caused by sickness in South Africa, as is almost always the case, were far in excess of those attributable to gunshot wounds and injuries received in action Still, the losses in the field from disease compare favourably with the previous war records of other nations or with those of some of our own in other campaigns. And this brings us to the main factor in swelling the list of sickness and mortality among the troops serving in the late South African war—namely, enteric fever

Much misapprehension apparently exists with respect to the history of enteric fever in South Africa and as to the part played by the Army Medical Service in regard to it. Briefly stated what are the facts? Enteric fever is, as we know to our cost from previous campaigns, a very common disease in that country The occurrences which led up to and culminated in, an epidemic outbreak in the recent war indicate that the disease, after it had once made its appearance among the troops at the Modder river soon grew apace. DE WET having left Natal for the relief (which he failed to accomplish) of CRONJE, who was enclosed as by a net at Paardeberg nevertheless succeeded in most seriously hampering the advance of Lord ROBERTS by his capture of the great convoy at Riet river This caused the soldiers of Lord ROBERTS's force to be put upon short rations and gave rise in order to replenish their stores and supplies to a delay of about two months at Bloemfontein and for some reason or other which has never been fully explained the waterworks in its vicinity were most unfortunately left in the hands of the Boers. Exhaustion and epidemic sickness on a large scale and attended with great loss of life rapidly followed as a matter of course. We are perfectly aware that the American Commission appointed to report upon the causes which led to the wholesale prevalence of enteric fever among the American troops in the Spanish war of 1898 found that infected water was not such an important factor in the spread of that disease as personal contact and pollution of the soil in and about camps. In the case of South Africa all these factors were also present, but that the chief and most operative among them was in all probability a contaminated water-supply no one reading the medical history of the events that followed Paardeberg can doubt. There was no railway or other transport available at the time to bring up all the hospital stores and supplies to meet a situation which was created and brought about by military and not medical causes Logically and dispassionately regarded it is not easy to discover how the unexpected movement of CRONJE's force to Paardeberg and other circumstances could have been foreseen and provided for If this be as we fully believe it to be, a correct description of the position, we cannot see why the Commander-in-Chief did not himself emphatically say so instead of leaving it to others who could not, of course, speak with his authority to declare it Had this been done we venture to think that the medical service would not in this matter have been made a scapegoat for occurrences which, however deplorable were outside and beyond its control.

◆

Physical Training and Defective Children

EARL EGERTON of TATTON in his inaugural address to the Sanitary Congress at Manchester dwelt upon the wisdom and necessity of providing means of healthy living in adult life and in the surroundings of childhood especially among urban populations. It is interesting to observe that while sanitarians have long endeavoured to deal with questions of sewage, of the construction of houses and roads, and of the prevention of infectious diseases and of fogs, there is now arising a desire to investigate more widely the conditions affecting the healthy physical and mental development of children and to found a scientific basis for the study of mental hygiene concurrently with sanitation. If the sanitary and educational authorities become one, as is anticipated it should follow that health of body and of mind will be equal objects of care. After describing the good sanitary work done in Manchester Lord EGERTON referred to the provision of open spaces as affording opportunities for recreation and games, for the full enjoyment of which town children need some preliminary training Physical training is now recognised by the Board of Education as a part of the school curriculum and it is recommended that this should be taught by the ordinary school staff. The usefulness of primary education will doubtless be increased by the general introduction of physical exercises and also by the development of sanitary surroundings, at the same time, this general advance in the conditions of school life and in the quantity and quality of work done will increase the necessity for provision for the benefit of those scholars who on account of physical or mental weakness, are unable to follow the ordinary school training Lord EGERTON traced the history of provision for defective children from their first official recognition as a class by the Royal Commission on the Blind, Deaf and Dumb of which he was chairman while the reports furnished to other commissions and public bodies on 100 000 children seen in schools by Dr FRANCIS WARNER were followed by the Education Act for Epileptic and Defective Children. Special schools and classes are now provided in most cities for the feeble-minded and crippled children, while those under the Poor law are received into resident homes provided for their care and education. The Childhood Society was founded in 1896 for the scientific study of the mental and physical conditions of children, and it is largely due to the amount of public attention which that society has directed to the subject that such advances have been made. A meeting of the society was held in Manchester on Sept. 12th under the chairmanship of Dr J KERR and the homes for the feeble-minded at Sandle Bridge were visited by members of the Congress

There is much work to be done in studying these sub-normal children and further accuracy in diagnosis and classification and in knowledge of the complications met with is much needed. Many pupils who are mentally dull, backward and in the opinion of their teachers, incapable of being trained are really suffering from deafness due to removeable causes or errors of sight while other cases are dull from the effects of heart disease or other physical disturbance The methods of caring for and training children who are either slightly defective in cerebral development or at a disadvantage from defect of the senses or organs, require to be worked out by the same scientific system of clinical research as has been applied to other conditions of cerebral disturbance. Briefly it may be said that all these children usually require to be trained to speak and to be controlled in all actions until they have acquired correct and social habits of response training should be conducted stage by stage, with the objec of obtaining control over the child's natural spontaneity and of encouraging his or her growth to coördinated action. If the teacher's efforts are mainly devoted to training action in the pupil rather than to implanting knowledge there is no reason why school life should not commence early, experience shows that useful attempts in adapting the defective child to social amenability are most successful when commenced at the age of three or four years. The defective classes differ in capacity for improvement, but even those who are not educable may be trained so as to prevent them from becoming offensive and harmful in adult life We are glad that Lord EGERTON gave prominence to the social importance of hygiene in educational life and that he directed the attention of sanitarians to the means of improving both the developmental standard and the mental potentiality of the people.

Annotations.

"Ne quid nimis"

THE ILLNESS OF PRESIDENT ROOSEVELT

WITHOUT fuller information it is impossible to speak with certainty of the nature of the lesion from which President Roosevelt has suffered, but apparently the accident at Pittsfield gave rise to a hæmatoma of the leg and this in its turn, by the separation of the fibrin, resulted in a cyst containing serum This was drawn off by an aspirator and in all probability no further harm will result, but hæmatomata at all stages have a tendency to suppurate and this tendency would be distinctly promoted by exercise The President, therefore, has wisely been advised to rest Though the condition in many of the reports has been spoken of as an abscess it does not appear that any suppuration has yet occurred

SCHOOLS FOR CRIPPLES IN LONDON

THERE are now eight of these schools, officially called "Physical Defective Centres," under the London School Board, their establishment following as a natural, but rather belated, corollary on the formation of special schools for mentally weak children People were naturally horrified to find that many maimed or crippled children, unable to attend the ordinary schools, were locked up alone the whole day while their parents were at work and ran a risk of never developing such brains as they had, others were mixed up in the schools for the mentally deficient. The first reform was made three years ago as a joint effort on the part of the Passmore Edwards Settlement and the London School Board, and this school we were enabled to visit a few days ago Children are admitted in the first place by the lady medical officer of the board and are regularly inspected every month, so that if they become fit they may be drafted into an ordinary school. A trained nurse is supplied by the board who fetches the children in an ambulance carriage in the morning, dresses any wounds which require it, compels the children to eat a substantial midday dinner, and takes them home again in the afternoon when lessons are done On the day of our visit 42 children were in attendance, 24 had been fetched by the ambulance, three had been wheeled to school by their relatives, and 15 had walked Each child pays twopence per day for an excellent meal of meat, vegetables, and pudding, and the lesson hours are from 9 30 to 12 A.M and again from 1.30 to 3 P M., the intervening time being spent in hobbling about, sometimes on crutches or digging in the sand heap in the Duke of Bedford's garden The children vary in age from five to 16 years, and after attaining the latter age those who are fit are apprenticed out to various sedentary trades by the After-training Committee At present five have been so started in the hope that they will by learning a trade be able to support themselves Half the children are in the infants' school, which the board calls 0 standard, and here they learn reading, writing, arithmetic, and some kindergarten work. The more advanced boys and girls learn all the board subjects from the first to the sixth standard, in addition to extra handiwork. The children are all attending different hospitals and are mostly suffering from spinal curvature, hip disease, infantile paralysis, tuberculous joints (chiefly the knees), and heart disease, both congenital and acquired after rheumatism The nurse tactfully advises parents with regard to cleanliness and to keeping windows open in the house Without in any way interfering with the out-patient treatment of the various hospitals it would be interesting if a register were kept of the weights of the children They ought to be gaining weight, but some of them looked very thin, and it occurred to us that possibly the substantial dinner might be followed by a ration of cod liver oil or its equivalent. For the school to become quite ideal marquees with a permanent roof and moveable wings should be erected in the spacious garden during the summer months so that all lessons could be done in the open air It must not be forgotten that every one of these cripples is predisposed to the onslaught of the tubercle bacillus

THE LUNACY PROBLEM AS IT AFFECTS LONDON

IN the thirteenth annual report of the Asylums Committee to the London County Council it is stated that the total number of pauper lunatics under the cognisance of the committee was, on Jan. 1st, 1902, 22,155, being an increase of 786 on the previous year This increase is the largest for any year since 1896 The fact that a portion of the parish of Hornsey became, through the provisions of the Local Government Act of 1900, attached to the County of London accounts for a small fraction of this increase, and the report states that with this exception the present considerable increase in the lunacy population still awaits explanation. On apportioning the figures among the different classes of institutions for lunatics it is observed that whereas the number of lunatics in workhouses or in the charge of friends and relatives has decreased by 30 the imbeciles in the asylums of the Metropolitan Asylums Board have increased by 40, and the pauper lunatics in the asylums and licensed houses of the County of London have increased by 776 The Asylums Committee, from a consideration of the statistics of the increase of insanity in London during recent years, is inclined to the belief that provision for accommodation as calculated by it—viz, to meet an increase of 500 per annum by building a fresh asylum to accommodate 2000 patients every four years—is justified On March 3rd, 1902, the Horton Asylum was opened for the reception of patients This asylum is built to accommodate 2000 patients—900 males and 1100 females—and the committee has now under consideration the necessity of proceeding with the construction of a new asylum, the ninth under the jurisdiction of the London County Council, to cope with the continued increase in lunacy As the result of inquiries made as to the type of building to be erected for this purpose the committee proposes to adopt for its ninth asylum "a modified form of the villa type, with central administrative buildings," and the council has voted a sum of £1000 for the preparations of preliminary plans in connexion therewith. From the collated medical statistics for the year ending Dec 31st, 1901, it appears that the total number of patients admitted to the asylums at Hanwell, Colney Hatch Banstead Cane Hill Claybury Bexley Heath and the Manor (Epsom) was 3621, which number comprised 1549 males and 2072 females. Of these 3226 were first admissions. The total number of cases discharged as recovered during the year amounted to 1054—viz 426 males and 628 females, or 7 2 per cent. of the average number resident. The deaths during the year amounted to 1270 or 8 6 per cent. as calculated on the same basis. Of the deaths 334, or 27 per cent. were due to general paralysis of the insane, and 160, or 12 6 per cent. were due to pulmonary and other forms of tuberculosis. From a comparison with the returns of the previous year it appears that the recovery rate has fallen slightly—viz. from 9 per cent. in 1900 to 8 6 per cent. in 1901, while the death rate has also fallen from 9 3 per cent. to 8 6 per cent. for the corresponding years Among the causes of insanity in patients admitted hereditary predisposition played the most important part, as it accounted for 987 cases, or 27 per cent. of the admissions, while alcoholic intemperance was responsible for 608 cases or 17 per cent. The weekly maintenance rate for patients was 11*s* 8*d*. per head, and in view of the continued high prices for provisions and stores the committee considers that there is no likelihood of a reduction of this rate. A report is appended by Dr F W Mott, pathologist to the asylums, giving a summary of the work done and of the researches in progress at the pathological laboratory at Claybury Asylum a full account of which will be included in the second volume of the Archives which the committee hopes will shortly be in the hands of the publishers. Various interesting charts and tables are included in the committee s report, one of the most important of these being a graphic chart in colours showing the steady rise in the proportion of lunatics to population in the County of London since the year 1889 the curves being drawn to scale on the basis of the census returns and the annual returns received by the Asylums Committee.

"PTOMAINE POISONING

IN our issue of Sept. 20th, p 825, we referred to the recent cases of poisoning by food which have been popularly attributed to the action of ptomaines. On Sept. 23rd the inquest into the circumstances attending the death of Joseph Swinson who died at Uttoxeter after eating one of the pork pies purchased at Derby was concluded. Professor Sheridan Delépine, who gave evidence, said that he had discovered both in the pies and in the bodies of those who had died after eating them, a bacillus belonging to the colon group, known as bacillus enteritidis Gaertner There was no evidence to show that the meat of the pies was contaminated but the jelly was full of bacilli and he presumed that it had become infected whilst exposed in the course of the preparation of the pies The person who sold the pies, however careful he might be, could not possibly tell that there was anything wrong with them. Food contaminated by this particular bacillus did not alter in either taste or smell. Professor Delépine added that he had inspected the building in which the pies were made and that there was every indication of careful management, but there were, nevertheless, several sources of possible contamination. Dr W J Howarth, medical officer of health of Derby agreed with Professor Delépine that Mr Cope the butcher from whom the pies were obtained managed his business carefully He went on to give several sources of possible contamination, such as a privy and ashpit a few yards away from the slaughter house. He could not say that Mr Cope had been guilty of culpable negligence, for he had not received any complaints concerning Mr Cope s premises from any of his inspectors However the case opened up the whole question of the management of such places of business and he intended to make important recommendations to the Derby town council. The jury returned a verdict to the effect that Joseph Swinson died from the effects of eating pork pie which had been accidentally contaminated by the presence of bacilli, but that, so far as the evidence went, no blame could be attached to any person engaged in the preparation of the pies. It seems to us that this case is one more argument in favour of the total abolition of private slaughter houses. Private slaughter houses in a large town are nothing but an anachronism and are always liable to lead to infection of food, cruelty to animals, and, in many cases to the sale of diseased or unwholesome meat. The public abattoir which is open at all times to the inspection of the sanitary authorities, which can be properly drained and which should be situated at a distance from other buildings is the only method of ensuring that our meat-supply shall be provided with as little suffering to the animals who afford it and with as great safeguards of the purity of the meat and of the health of those who consume it as is possible.

DUTY AND DEATH

A SHORT paragraph with the above heading which appeared in one of the Manchester papers on Sept. 13th seems worthy of notice. It states that Samuel Short, aged 50 years, an engineer whilst lowering 24 men down a coal pit at Tyldesley had an apoplectic seizure, but with great presence of mind stopped the engines. He died almost immediately It is difficult for anyone to put himself mentally in this poor fellow s place, but whatever his sensations may have been his first thought was to secure the safety of the 24 men whose lives he held in his hands. He must have felt that what had to be done must be done quickly and his action taken at once, showed that in his last moments of consciousness his movements were directed by his care for the safety of his fellow men and not for his own life

A REMARKABLE CASE OF FAMILY DEGENERACY RESULTING FROM ALCOHOLISM

IN the *Quarterly Journal of Inebriety* for July last Dr A. MacNicholl of New York publishes an account, together with a genealogical table of a family in which the results of degeneracy and disease, arising mainly from alcoholism, have been traced and studied for four generations. The investigations of the various members which comprised this family tree were carried out with great fulness of detail and the facts ascertained constitute a striking illustration of hereditary sequelæ of alcoholic intemperance. The first generation comprised a married couple of good social position in the United States. The man was a well to do and respectable merchant of English parentage while his wife was of Huguenot descent. Both indulged in social gaieties, lived well, and took wine habitually and daily They had two daughters, each of whom developed in early life a fondness for wine and spirits. The elder of the two gave herself up to alcoholic and sexual excesses of the wildest description, became the mistress of various men, and contracted loathsome venereal diseases. She died a raving alcoholic maniac at the age of 40 years. The second daughter married a wealthy banker and indulged in a very gay life full of excesses which led to a temporary mental breakdown at the age of 35 years. She bore eight children, two males and six females. The two males grew up to be drunkards and were at the date of publication of the above article alive and aged respectively 50 and 60 years. Of the six daughters five died from phthisis between the ages of 20 and 35 years. The surviving daughter married a man of good position who was healthy and a moderate drinker They led a fashionable and eventually a fast life, observing few social restraints She became a drunkard and an opium-eater and ended her days in poverty Of this union 17 children were born, constituting the fourth generation Ten of the 17 children died from phthisis below the age of five years The seven surviving children showed the following remarkable histories The eldest, a female, showed great moral perversion as a girl, became a concert-singer and female prize fighter, led a drunken and immoral life, and was the mother of several illegitimate children The second, a male, became a moderate drinker and showed signs of phthisis, but was alive when last seen, at the age of 45 years. The third, a male, became an insurance agent. He was a moderate drinker and showed suicidal tendencies on more than one occasion. The fourth, a male, became a habitual drinker and morphia eater, had delirium tremens several times, and ended his life at the age of 35 years by an overdose of morphia taken whilst drunk The fifth, a female, married early, took to drink, and developed suicidal-mania. The sixth, a male, exemplified in his life all the characters of a psychopath Thus at 12 years he was an industrious and studious boy but peculiar in his ways, at 16 he was a moderate drinker, at 21 he married, but showed himself to be lazy, indolent, and neurasthenic, at 23 he was a confirmed drunkard, neglectful of his home, at 24 he abandoned his wife and two children, and at the age of 28 years he committed suicide by drinking carbolic acid. The seventh and last member of this unfortunate family of degenerates was a male who received his education in a high school and who at the age of 21 years was the subject of moral perversion and suicidal impulses The whole family tree during the four generations traced above thus exhibited all forms and grades of mental degeneracy and deterioration in a remarkable manner

SAMSU

SAMSU is an alcoholic beverage used in Eastern Asia and is, in fact, a variety of arrack, being obtained by the distillation of a fermented liquor prepared from rice. A description of samsu, as well as of the characteristic fungus used in its manufacture, was given by Mr B T P Barker on Sept. 17th at the meeting of the British Association at Belfast He said that rice was boiled in water and after cooling a powdered substance which caused fermentation was added to the mixture At the end of this fermentation the liquid was subjected to three successive distillations, the final product constituting the true samsu and containing a high percentage of alcohol. The powdered substance was sometimes made up in the form of small round greyish cakes One of these was obtained by Mr D T Gwynne Vaughan at Singgora during the Skeat expedition to the Malay Peninsula, and Mr Barker was indebted to him and to Mr R H Yapp for an opportunity of examining it and for information concerning the manufacture of the spirit. The composition of the cake was a secret but there were apparently several ingredients of which pepper and fruit of some kind formed a part. On adding a portion to boiled sterilised rice a fungoid growth soon appeared and a red or purple colouration was produced. This was due to a species of monascus A bacterium capable of fermenting glucose had also been isolated The biological processes on which the manufacture of the spirit depended were the conversion of the starch of the rice into fermentable sugars by fungi, in particular by a species of monascus, and the alcoholic fermentation of these sugars by a bacterium, and possibly also by wild yeasts. Monascus was one of the simplest sexual ascomycetes but the genus had been placed in the hemiasci on account of a supposed formation of spores in a sporangium, surrounded by an investment of hyphæ.

CHOLERA IN EGYPT

THE Director General of the Sanitary Department of Egypt reports that for the week ending Sept 8th, 7758 cases of cholera had been notified, during the week, 3469 of these were found dead out of hospital and 2863 deaths took place in hospital During the week 131 cases occurred in Cairo and 133 in Alexandria, against 149 in Cairo and 18 in Alexandria in the previous week Up to Sept. 8th the authorities had notification of 1168 towns and villages being infected throughout Upper and Lower Egypt.

THE RELATION OF SCIENCE TO ART IN REFERENCE TO TASTE AND BEAUTY

SIR SAMUEL WILKS has republished in pamphlet form a very interesting lecture which he recently delivered to the Hampstead Scientific Society[1] The subject is a large one on which much could be said on many sides and it is inconceivable that any two people would agree on all the questions which might arise out of it. It has long been, and is likely to remain, a common subject of table talk and of general conversation, especially at those social gatherings at which physicians and artists meet. The analytical spirit which is common amongst the votaries of science is, as he says, antagonistic to the emotional and artistic temperament. From the artistic point of view this fact was once very happily expressed by an inmate of the Bethlem Hospital who gave it as his opinion that "an analysis of the emotions is a filthy process" Sir Samuel Wilks deals with a very popular subject of dispute when he discusses the relation which exists between the utility and the beauty of buildings He does not agree with Ruskin in disliking the London terminus of the Midland Railway Company, which, "being Gothic, suggests an ecclesiastical edifice." Ruskin's criticism cannot be adequately expressed in so crude a form, and however erroneous his teaching may have been Ruskin had at least some knowledge of architecture and was aware that many of the finest public buildings are Gothic and not ecclesiastical He disapproves the admiration which Ruskin expressed for what he calls "continental patchwork churches, however irregularly built, because they were put together piecemeal as necessity dictated." "Patchwork churches" is not a happy phrase and many of the buildings which he would place in this category are of the greatest interest not only to all those who admire beautiful things but also to archæologists, and ecclesiastical archæology is more a science than an art The interest to the archæologist is an intellectual one, and archæology, like anatomy, has a pathological side The paper is so suggestive in every direction that it appears to invite digression, but on the question of architecture we must be content to suggest that the works of Pugin might prove of interest to the writer, they deal with some of the questions he raises and, as a matter of general principle, utterly condemn the idea of shams, or what he, perhaps derisively, calls "the modern cultivated taste" for a veneer of lath and plaster It is hardly likely that the Hampstead ladies agreed with all the remarks in the lecture. The author maintains that "the gait displays the woman of breeding" Ladies will probably take no exception to that This dictum is, however, followed by a rather curious theory, founded on observation, as to the gait of maid servants The theory is briefly this Spanish and Italian ladies have high insteps, this is supposed to show high breeding, hence the fashion for high heels, whence comes a habit of the middle and lower classes of life of clamping their heels as they walk along" Sir Samuel Wilks found that his maids when they walked along his hall clamped loudly enough to be heard throughout the house, influenced no doubt by a feeling of superior dignity' Most ladies would probably give a different explanation of these phenomena. It is perhaps a little doubtful whether either science or art properly so-called has any relation to women's dress or for that matter to men's dress. He discusses the perennial question as to whether there is a standard of beauty existing in the human mind and he favours the negative view on the ground that the Hottentot and the Greek ideals are not identical. He quotes Ruskin's opinion that why we receive pleasure from some forms and colours and not from others is no more to be asked or answered than why we like sugar or dislike wormwood Darwin was unable to account for the fact that many men and animals delight in brilliant colours. The story is told of the lady who informed Turner that she had never seen such a sunset as one he had painted and to whom he exclaimed I dare-say you wish you could." The author remarks that this is called genius or a spark of the heavenly fire. It appears possible that Turner may have meant to be sarcastic and the story is not unlike that told of the young lady who asked the Duke of Wellington whether he was not surprised at Waterloo No but I am now was the reply We trust that the lecture will have a circulation far beyond the metropolitan borough—for it must no longer be called the ' charming suburb —in which it was delivered

---

[1] The Relation of Science to Art By Sir Samuel Wilks, Bart M D, LL.D F R S Hampstead: Sydney C Mayle 1902

THE FEEDING OF INFANTS

AT the Battersea Coroner's Court on Sept. 22nd Mr B Henslowe Wellington held an inquiry into the death of Frederick William Adams, aged five months. Evidence was given by the parents that as the child did not seem to thrive on cow's milk he was fed on a patent food which was sold in packets The mother said that she first gave the child the food on Sept. 7th and that afterwards she saw about half a dozen maggots in the powder The child got worse and she took the food back to the druggist who had supplied it. The sanitary inspector to the Battersea Borough Council said that he saw the maggots in the food in Adams's house and that he then went to the druggist's shop where he found five packets of food containing maggots. Mr William Robinson, who had attended the child, said that he thought that death was due to convulsions caused by epidemic enteritis the result of improper feeding Even if the food had not been maggoty it was not a suitable food for an infant five months old. The jury returned a verdict in accordance with the medical evidence but added a rider to the effect that the food should form the subject of further inquiries We do not suppose that the maggots had anything to do with the death of the child for they probably actually were or else were something allied to the ordinary meal worm. Neither do we know what particular patent food the unfortunate child was fed upon but, as we have said over and over again the practice of feeding children upon patent foods which in the majority of instances are nothing but starch or starch derivatives is one of which no condemnation can be too strong When in addition they are dirty and contain the ova or larvæ of insects they are more unfit than ever for the purpose of human food. The provisions of the Food and Drugs Act are very fairly stringent but the penalties for adulteration should be made a great deal heavier than they are. We suppose it is impossible to prevent accidental contamination of food, but it is quite evident that the particular food in question must have been contaminated before being put up into packets and we hope that when the jury's recommendation is carried out the premises of the manufacturer who supplied it will be made the subject of a most searching investigation.

THE GERMAN RED CROSS AMBULANCE IN SOUTH AFRICA

THE total number of patients treated in the German Red Cross Hospital during the late war in South Africa was 1358, of whom 707 were in patients The mean duration of the cases was 11 days. 70 cases of 'abdominal typhus (enteric fever) and 108 of dysentery were treated in the ambulance. The author of the report Dr Matthiolius believes that flies play an important part in the dissemination of the former disease and he is also of opinion that gastro-intestinal affections are widespread amongst the Boers Malarial diseases were comparatively rare 33 cases in all having been treated. 487 wounded men were attended to but with the exception of trephining only a few capital operations were performed. As far as he can judge there is very little to choose with regard to severity between the injuries resulting from Mauser and Lee Metford bullets In wounds of the thorax due to the latter the prognosis may have been somewhat more grave and possibly a tendency towards suppuration may have been more frequently observed in those of the brain In summing up Dr Matthiolius gives it as his emphatic opinion that explosive projectiles were not employed on either side. The stories about poisoned bullets are equally devoid of foundation and there is likewise no truth in the reports that lyddite fumes produced injurious effects. Lyddite shells were easily recognisable by the yellowish green colour of the fragments which seldom exceeded from four to six in number The latter circumstance fully accounts, in Dr Matthiolius's opinion, for the rarity of the wounds that could be attributed to the ' famous lyddite bombs.

SYMPATHY WITH PROFESSOR MURRI

IT seems but yesterday writes an Italian correspondent under date, Bologna, Sept. 15th that Augusto Murri celebrated the first 25 years of his tenure of the chair of clinical medicine in our university amid the congratulations of pupils and compatriots from far and near and to-day he is receiving messages of sympathy and condolence from the same hearts and hands under the most dreadful, the most desolating calamity that can befal the head of a household. His son Signor Tullio Murri, a young man of high ability and varied culture destined to shed lustre on the Bolognese bar the proud participator in his father's honours at the jubilee above referred to is a fugitive from justice, having confessed through the medium of his unhappy parent to the murder of his brother in law Count Bonmartini, in this city on August 28th—a crime in which Professor Murri's daughter the Countess Bonmartini is charged with having assisted her brother and for which she is now imprisoned at San Giovanni à Monte Other arrests for complicity in the murder have been effected—one if not two, of the accomplices being I regret to say medical men—while the judicial authorities are steadily and indefatigably following out the clue which they believe they have in hand towards the solution of the mystery Till they think fit to formulate the charge or charges which seem inevitable it were idle and indecorous for the layman however interested, to attempt to solve it All the same the Italian press for which such horrors have a morbid fascination fills its columns from day to day with the results of interviews more or less authentic, of individuals more or less likely to have some cognisance of the facts Such a breach of the reticence binding on the higher minded journalist I have no intention of committing At the proper time I may give your readers a summary of the indictment and the verdict. Meanwhile, they will join, I am sure, in the message of sympathy, reinforced from every quarter at home and abroad, with the illustrious pathologist and exemplary citizen who, in the zenith of a brilliant and useful career, lies crushed beneath a domestic visitation as sudden and as appalling as ever inspired the tragic muse of Greece "

THE DISTRIBUTION OF PLAGUE

THE Director General of the Sanitary Department of Egypt reports for the week ending Sept 7th that there were 5 new cases of plague admitted, all of which occurred at Alexandria. The deaths numbered 2 and the recoveries 2. The sanitary measures carried out were as follows 6562 rooms were disinfected and 428 were limewashed, 308 sacks of effects were disinfected and 6460 sacks of rubbish were burned The number of rats killed and burned was 167 As regards Hong Kong a telegram from the Governor, received at the Colonial Office on Sept 18th, states that no case of plague had occurred within the previous 10 days With regard to Cape Colony the medical officer of health reports that for the week ending August 23rd no case of plague had been discovered at any place in the colony but that a number of rats dead from plague had been discovered in a forage-store at Port Elizabeth on August 24th For the week ending August 30th, however, the medical officer reports that there had been no case of plague in either man or rat discovered at any place in the colony

AMERICAN "CULTURE" AND "CHRISTIAN SCIENCE"

JUDGING by numerous instances, we are sometimes tempted to inquire whether whole civilisations are plunging down the dark slope that leads, in the case of private individuals to the lunatic asylum The degenerate side of the American mind—its *megalomania* and shoddy mysticism —has long interested students of sociology, but interest becomes grieved astonishment when we find an apparently decent American literary and philosophic journal turned suddenly into an exponent of a murderous heresy The *Conservator*, published in Philadelphia, has always maintained a high reputation for the quality of its matter and manner It has been amiably notorious too, for its imitations of Walt Whitman, whose quite inchoate "philosophy" the journal aims at "conservating" But now, in an editorial article, the ghostly influence of the author of the "Ode to Lincoln" is pressed into the service of "Christian Science" in a manner as decadent as it is likely to be harmful The article is at once a eulogy of, and a rhapsody over, two recent American books with typical titles "The Truth in Christian Science" and "How to Get Acquainted with God"! Here is a specimen, some way after Whitman, America's one world poet.

> The drug is a confession We resort to it in the extremity of our ignorance and lack of faith And the drug will go because all disease that does not disappear will yield to a direct spiritual effluence We are cowards trembling before the mays and mustnots of the physical world .. Only the soul is convincing We only begin to see what the mind can do with the body The mind, that makes of God and man the unified substance of immortality It would be rash to set any limit whatever to the ability of the mind to take care of man The mind that is man The mind will do all the good the drug will do and will not do the harm the drug excites The scoffers scoff But meantime man is gaining in self acquaintance and self acquaintance will in its consummations retire all grosser forms of physicianly counsel " -

Thus speaks the new Jefferson Brick. Even if read aloud with a gentle nasal twang to suggest Boston "culture" the stuff remains dangerous It could be passed over, however, were it not put forward in a *format* and with pretensions reminiscent of our own best reviews Philadelphia has a great past in medicine, social reform, and humanitarianism, and poor old European Germany has fathered Kant, Goethe, Virchow, and others, and even when damaging the world's "moral currency" has done so robustly in the person of a Bismarck. It is melancholy, therefore, to find a Philadelphian editor with a German patronymic—Mr Horace Traubel—openly disseminating the views above quoted Their weird English and scant sanity do not render them less misleading What would be said of England were Mr Knowles or Mr W L Courtney suddenly to turn quack doctors in the columns of the great reviews which they direct ?

ACROMEGALY AND GIANTISM

A SOMEWHAT new and interesting light was thrown from an anthropological point of view upon the question of acromegaly in its connexion with giantism by some papers read at the late meeting at Belfast of the British Association for the Advancement of Science by Professor D J Cunningham, F R S, and Professor A F Dixon Professor Cunningham's paper was on Cornelius Magrath, the Irish Giant, whose skeleton, by permission of Trinity College, Dublin, was exhibited, and the paper by Professor Dixon was in connexion with a skull modified by acromegaly Magrath, who was seven feet five inches in height, was born in Tipperary in 1736 and died in Dublin in 1760 He was exhibited in all the principal cities of Europe as a giant The picture of this giant as drawn by Professor Cunningham's conception of him when living presented many points of alliance with acromegaly, and in Professor Cunningham's opinion supported the idea that giantism was a morbid process closely allied to that disease He upheld the view advocated by Dr Woods Hutchinson that giantism and acromegaly were virtually the same morbid process, differing according to the time at which the disease made its appearance If the individual was attacked in early youth before the skeleton was consolidated there was a more or less uniformly excessive growth of the limbs and enlargement of the face and a giant was produced, if attacked after 26 years of age when the skeleton was consolidated acromegaly resulted, with enlargement of the face, hands, and feet, and the other physical changes indicative of that disease. Professor Dixon exhibited a skull modified by acromegaly and observed that it showed an extraordinarily large face associated with hypertrophy of the pituitary body Up to the present time no satisfactory explanation has been given as to why a pathologically enlarged pituitary body should be associated with an enormous development of the face Professor Dixon went on to refer from an anthropological point of view to the historic and folklore record about acromegalic and giant and to trace out various points of resemblance Moreover, in further elucidation of the subject we may call attention to another paper read by Professor E A. Schäfer on the Diuretic Action of Pituitary Extracts, diuresis being often present in acromegalic subjects It is not the first time since Marie called general attention to the disease in 1886 that the points of similarity between the partial giant growth seen in acromegaly and the universal form of growth present in giants have been noticed But it has been commonly held that there was this important distinction between them—namely, that whereas the one was a morbid process and constituted a disease, the other giving rise to giantism was simply an over-development of a normal process This is not, however, the view that was apparently taken by the authors of the papers read at the meeting of the British Association, who regard them both as merely varieties induced by different conditions of one and the same morbid process. Physiology has only, however, to overstep its limits to give rise to a perverted tissue-nutrition and to become pathology

In a typical example of acromegaly which not long ago came under our observation all the features of the disease were at that time well marked but it was at first erroneously regarded as a case of rheumatoid arthritis. The patient's attention was specially directed to the progressive enlargement of his hands by his having so frequently to provide himself with larger sized gloves. The subsequent appearance of changes in the face, feet and bony skeleton, with the facial physiognomy and other symptoms indicative of acromegaly left no doubt as to the diagnosis. But much still remains to be ascertained about the nature and pathology of this disease and the nature of its relation to the pituitary body

LECTURES AT THE MEDICAL GRADUATES COLLEGE AND POLYCLINIC

A SOMEWHAT novel scheme, and one which has *primâ facie* much to recommend it, is we are informed, in process of realisation at the Medical Graduates College and Polyclinic. The proposal is to have a long possibly interminable, course of lectures on medicine, surgery and their allied specialities in which every member of an association of lecturers shall take a subject to which he has given special attention. Thus it will constitute a sort of *vivâ voce* encyclopædia of which new and amended editions will be constantly appearing The lectures will be systematic as distinct from clinical and good summaries of up-to-date knowledge are desired rather than original views For the latter the college considers that it has already made ample provision. The arrangements for the first series of this course (to extend from October to Christmas) have been completed Sir William Broadbent is to lecture on the Pulse, Dr Patrick Manson on Dysentery and Sprue Dr Theodore Williams on Pulmonary Tuberculosis Dr Seymour Taylor on Enteric Fever Dr James Taylor on Tabes, Dr Judson Bury on Peripheral Neuritis, Mr James Cantlie on Plague, Mr C B Keetley on Coxa Vara, Mr J Hutchinson on Syphilis, and Dr T Colcott Fox on Lupus. The fee for the course of 22 lectures will be one guinea and the council has decided to reserve a certain number of tickets for women practitioners who will be admitted also to certain other lectures given in the college. There will now be a lecture on some subject every afternoon except Saturdays at 5.30 P M. The council has under consideration the practicability of admitting fifth year students also to these lectures Members of the college are of course free, but neither students nor ladies are eligible as members.

HELP FOR THE WOUNDED IN NAVAL WARFARE

IN order to meet the requirements of the wounded in naval battles, which in his opinion are perhaps now nigh at hand Dr Duclot of the French navy suggests in the *Archives de Médecine Navale* for August last, that dressing bags should be served out before the decks are cleared for action, the care of them being entrusted to trained men if possible, but should none be available, to responsible warrant or non-commissioned officers. 'Five minutes of explanation and demonstration would suffice, he thinks to render these men, usually so handy, well nigh as skilful as he is himself in the application of the appliances and dressings Under the conditions of modern warfare it will be quite as impossible for medical officers to continue to visit the different parts of the ship during the heat of an engagement as it will be to convey the wounded to the hospital The definitive treatment of the wounded must necessarily be postponed until hostilities are ended or suspended, but if the means of affording first aid could be made immediately available it is certain that a great many valuable lives would be saved and also that the wounded men, when at last they came under the surgeon's hands would be in a far more favourable condition to undergo operations than if their injuries had remained unattended for a considerable period of time. Dr Duclot gives a list of the articles which he thinks should be provided in each dressing bag and adds Everything which enters into the composition of our modest ambulance-sack is to be found on board a man-of war A few days should suffice for the construction of the cases under the orders of the commander as well as for the teaching of all concerned by the medical officer and that without occasioning the expenditure of a single centime."

THE borough council of Lambeth at its meeting held on Sept 18th unanimously voted to the medical officer of health, Dr J Priestley an honorarium of 100 guineas in recognition of the energy and skill displayed by him in dealing with the epidemic of small pox within the borough of Lambeth.

A complimentary dinner to Professor W Erb of Heidelberg to be given by the medical staff of the West London Hospital will be held at the Trocadéro Restaurant on Saturday Oct. 11th at 7 30 P M Dr Donald W C Hood, C V O will be in the chair

THE testimonial to Mr Edmund Owen subscribed for by past and present students of St Mary's Hospital will be presented on the occasion of the annual dinner to be held at the Whitehall Rooms Hôtel Métropole, on Friday Oct 3rd

SLEEPING SICKNESS IN PRINCE'S ISLAND AND THE PROVINCE OF ANGOLA

THE following is an abstract of the report of the Portuguese Commission on Sleeping-sickness (Sleeping Dropsy African Lethargy Negro Lethargy) in the Ilha do Principe (Prince's Island) and the Province of Angola (1901)

Sleeping sickness is supposed to have been imported from Gaboon by the slaves who were brought from that country to the regions above mentioned before 1799 and who, by marriage with the people of Angola, originated the inhabitants of Prince's Island. Before 1887 there were but few cases of this disease and the increase of it in the last few years is doubtless due to the great importation of coolies from the infected parts of the West Coast of Africa, for many of them are suffering from the disease when they land and these have had every opportunity of infecting their companions, accommodation on board ship being as bad as possible.

In the island the exciting causes of the disease appear to be defective nourishment, excessive labour and want of hygienic care in clothing and lodgings Alcoholic excess and smoking of *liamba* cannot be causes because neither is possible

All the negroes of either sex and any race who come to the island are liable to be attacked, except children under three years of age and old people, but there are very few old people. The season of the year and the place of abode make no difference in the spread of the disease which attacks about 2 6 per cent. of the negroes in infected stations. A case is detailed from which it appears that the disease may be contagious to those who eat together and these people eat from the same bowl with their fingers and lick their fingers. Wives and children do not eat together with their husbands and fathers

No facts could be ascertained about the period of incubation The onset may be sudden and marked by furious delirium, with sometimes homicidal tendencies but commonly there is a prodromal period of general malaise weakness of the lower limbs loss of appetite, incapacity for work in normally active persons, and finally somnolence these symptoms are accompanied by spinal pains and occipital headache. Impotence in males and amenorrhœa in females are constant early symptoms. As to the duration of the disease, cases of speedy death were heard of but could not be verified, as a rule, those attacked do not die within 20 days and the average duration is two or three months, though some cases outlive a year. The average death rate of the island in 1900 was 175·4 per 1000—i.e., 67·4 per 1000 of Europeans and 179·6 per 1000 among the blacks, out of 821 blacks who died in the year 48 deaths were owing to sleeping sickness, but this proportion is probably much too low, the causes of death being carelessly tabulated.

The symptoms of sleeping sickness are notable disturbances of the lymphatic, nervous, and circulatory systems and of temperature. There is always as an early symptom congestion of the lymphatic glands, sometimes local in the mylo-hyoid or anterior or posterior cervical regions, but sometimes general throughout the body. These enlarged glands are variable in size, indolent, non adherent, moveable under the skin, hard, and with no tendency to suppuration or changes in the superjacent skin, the intermediate lymphatic vessels are rarely congested. Sensibility to touch remains unchanged until the final stage of complete lethargy. Sensitiveness to pain is also unchanged except that it is sometimes increased. The power of distinguishing between heat and cold remains, though sometimes dulled in the lower extremities. Muscular sensation and consciousness of passive movements remain perfect. There are no subjective disturbances of sensibility beyond the general cutaneous pruritus on the trunk and limbs which seems to be independent of whatever eruptions may appear through mechanical irritation or infection. Patients do not complain of formication, numbness of the limbs, or lightning or other pains, except of headache, which is transitory and not severe. There is no important disturbance of the senses, they hear, smell, and taste up to the last moment. Vision is preserved, but those who can read complain that their eyes are soon tired so that the letters dance, but this trouble disappears after rest and is not due to any fault of refraction.

The superficial and deep reflexes show different modifications according to the period and form of the disease. When signs of nervous depression do not accompany the commencement of the disease, as was observed in one case in which everything was an excuse for laughter and other signs of noisy joy, the reflexes are increased. Later, in spite of profound mental depression, somnolence, and want of power to rise from the bed, the reflexes may remain exaggerated, accompanied by muscular atonicity, and a kind of contractions which are comparatively easily overcome and allow of active and passive movements of the limbs. Absence or marked diminution of the cremaster reflex accompanies the loss of power of erection. The Argyll Robertson sign was not observed in any case. The reaction of the iris to light remains normal up to advanced stages of the disease, in these stages the pupils are in general dilated, reacting sluggishly to light, and after a series of slight contractions of the sphincter returning to the former degree of dilatation, although still exposed to the light. The conjunctival reflexes are retained up to the end.

In all the patients there were muscular tremors, which were generally slight and of slow rhythm and did not appear at the very commencement of the disease. At first these were merely contractions of isolated fibres, now in one muscle, now in another, which caused no movement of the limbs, these became a little more marked, causing contractions of the whole of some one muscle, with slight tendinous jerks, which could be seen and were easily felt, finally, these tremors became definitely established and produced rhythmic oscillations of the limbs, trunk, and at last of the face, the intensity varying during the day. The fingers did not show the slight individual tremor of alcoholic subjects. The tongue was sometimes the seat of fibrous contraction, quite visible when it was put out. The extrinsic muscles of the eyes were sometimes affected by these muscular tremors and the globe of the eye occasionally showed oscillatory movements. These tremors ceased in the final stages.

In the early phases of the disease all movements were possible and coördinated. The patients walked and could even run with ease, and execute delicate movements well, such as tying and untying their shirts, but were soon tired, especially in the lower limbs. Gradually walking became slower and more difficult, till at last they could not walk or even stand. Romberg's symptom was never present. There was no paralysis even when the patients could not leave their beds.

There were no convulsions or marked contractions, but sometimes rigidity of the nape of the neck, which was easily overcome, and, to some extent, hypertonicity of the muscles of the limbs which produced to the touch a sensation of hardness of the muscles, though it did not interfere with active or passive movements, in these cases pressure of the muscles caused pain. There was no pain on pressure of the nerves in any part of their course. There was no atrophy of the muscles, excepting in the final stages, when bed sores were formed. The somnolence might be overcome at first but later became irresistible so that patients fell asleep with their mouths full of food. The frequency of the fits of somnolence did not increase regularly, there were days together when this symptom was exaggerated and then other periods when it was less marked but these intervals became shorter and rarer as the disease progressed, until at last the sleep was almost continuous but not so deep that the patients could not be roused pretty easily, though they quickly relapsed into torpor when left in quiet. The eyes had a less lively expression and the upper eyelids drooped slightly. The sleepy state before death resembled the coma which precedes death in many debilitating diseases. One patient became furious if hindered in some stupid action, another was melancholy and continually crying, whilst a third was unnaturally and foolishly hilarious and then suffered a period of torpor and deep cerebral asthenia. In the early stages there was no marked mental change, but later there was remarkable depression of mind. Even up to the final stages patients understood questions perfectly and answered them correctly, but the answers were morose and in advanced cases reduced to a few words or even to one. (The surviving patients in Lisbon, however, smiled on being roused and spoken to and were pleased at a present of a cigarette.)

The memory was but slightly affected if at all. Volition was evidently influenced by the somnolence, as that increased, the energy for acts of volition diminished, and was finally almost *nil*. Patients had progressively increasing difficulty in concentrating their attention on what they were doing. The two patients who were more enlightened than the rest—one a mulatto and the other a black—stated that reading, writing, and other intellectual occupations became difficult to them because of the rapid fatigue of the brain and of the somnolence which this easily induced. There was no real interference with speaking or writing, no paraphasia, jargonphasia, or any other important change, but speech might be somewhat tremulous when the tremors were intense.

Diminution of arterial tension was a constant and very early symptom, in some cases tension became so low that Potain's sphygmo manometer would not record it. The pulse was at first small but equal, rhythmic and of normal frequency, but later it became unequal, usually fast, and at last irregular and thready. There was no arterio sclerosis. No abnormal heart sounds were heard and the most common modification of the normal sounds was diminution of intensity of the first over the mitral and tricuspid valves, at times the second pulmonary sound was more accentuated than the second aortic. In the advanced stages there was generally tachycardia with more or less marked embryocardia. The percentage of hæmoglobin in the blood was always diminished, ranging between 8·19 per cent. and 10 per cent. No abnormal forms of the red or white corpuscles could be distinguished. In no case was the filaria perstans found which Manson discovered in several cases.

There is no regular variation of temperature in this disease, the temperature may rise (generally in the evening) from time to time to 100·5° or 102° F. At the approach of death either the temperature rises to 104° or higher, or more often it sinks as low as 77°. In the only case of which a chart is given in the report the morning temperature fell to 77° two days before death, rose steadily to 84° the next evening, and fell again to 81° the next morning, when the patient died. In this case the temperature had not reached the normal for 15 days and had steadily fallen from 93° for eight days before death. In some cases pulmonary hepatization with rise of temperature occurred. The respiratory rhythm is usually maintained unchanged until the end even when the heart becomes irregular, but in the cases where the temperature falls in the marked way described above two or three respirations are followed by prolonged pauses. In general there is no disproportion between the pulse and the respirations.

There is no running at the nose or other symptom of morbid change in the pituitary mucous membrane nor are there any lesions of the pharynx, gums or teeth except occasionally slight mucous inflammation in cases with malarial taint The tongue is always somewhat coated but moist the tonsils are not enlarged and there is no profuse salivation. Occasionally in young children one-sided parotitis appears without fever or salivation The patients have a good appetite until the end, they do not suffer from vomiting or nausea; but there may be sometimes diarrhœa or even dysenteric symptoms but these are common in those latitudes independently of this disease At times in young patients gastro-intestinal tympanites is marked but on the other hand the abdomen may be depressed and hollow as in cases of meningitis The liver is never diminished but sometimes increased in size—always when the spleen is enlarged—and the surface of the liver is smooth to the touch. No biliary pigment is found in the urine though there may be icteric colouring of the mucous membranes The spleen is frequently enlarged to beyond the edge of the ribs but is moveable and not painful. The urine almost always contains a slight amount of albumin and casts may be found in the sediment as well as urobilin in excess. Quantitative analysis of the urine could not be made owing to disobedience of the patients. In some cases there was an appreciable diminution of urea and phosphates with a low specific gravity but no notable polyuria. Emaciation is very marked as the disease progresses to its end

The most important fact revealed in the necropsies was the constant presence of infra arachnoid exudation and in consequence increase in quantity of the cephalo-rachidian fluid in the ventricles and subserous spaces, which in cases that had a rapid course assumed quite remarkable proportions This fluid was never transparent but more or less turbid though not purulent. This exudation was evidently owing to a meningo-pia arachnoid inflammation variable in intensity and rapidity of progress. The arachnoid was slightly and unequally thickened cloudy or opalescent in some parts the pia mater was congested but not uniformly These lesions predominated always on the convexity of the hemispheres and especially from the posterior third of the first convolution to the occipital extremity of the brain and more markedly at the level of the paracentral lobes. In the cerebellum these lesions were chiefly found on the monticulus cerebelli. This localisation was more evident in the cases where the progress of the disease had been slow the inflammation extended then to the dura mater and there resulted adhesions of this to the subjacent meninges sometimes difficult to remove and when removed there remained yellowish mammillated irregular patches more or less large which were foci of secondary pachymeningitis There were no adhesions of the pia mater to the cerebral substance. On the lower surface of the cerebrum and cerebellum the cephalo-rachidian fluid, thus modified in appearance and transparency naturally accumulated in the sub-arachnoid spaces and on the anterior surface of the bulb and pons Varolii. On cutting into the brain in cases in which the meningeal congestion was more marked and the exudation sanguinolent punctiform hæmorrhages were found in the white matter but of no great extent. In the ventricles there was an increased quantity of fluid of the same character as that which accumulated on the convexity of the hemispheres. Only once were adhesions of the ependyma observed in the left lateral ventricle a little above the foramen of Monro The central ganglia in general retained their normal consistency only in one case in which all the cerebral substance was softened, the optic thalami and corpora striata were also softened. In another body on the internal aspect of the left optic sheath a small yellowish zone of diminished consistency was noticed The grey commissure was with one exception always decidedly thickened. In the cerebellum beyond the predominance of inflammation in the superior vermiform process no pathological change was visible to the naked eye, except in one case which showed in the right hemisphere general diffluence in all the central white matter On opening the rachidian canal there was frequently observed meningeal congestion, always more marked in the pia mater and in it generally predominating in the lower half of the medulla. The cephalo-rachidian fluid always of the same character as that which was found in the brain, constantly accumulated in the sub-arachnoid space at the level of the terminal portion of the medulla and the cauda equina. In one body, besides these usual pathological changes, there was general cysticercosis, a large number of cysts being found in the substance of the encephalon, and in the jejunum a very thin tænia.

The only fairly constant morbid changes in the heart were the yellowish colour of the surface and thickening of the muscle. There were no signs of endocarditis and seldom lesions of the pericardium. Apart from old pleuritic adhesions there was mostly nothing abnormal in the respiratory organs but in two cases extensive pulmonary infiltration had produced long areas of red hepatisation, another case was complicated with pulmonary tuberculosis Congestion of the tracheo-bronchial glands was frequent The spleen sometimes enlarged sometimes diminished was always of a lead colour, slightly tinged with purple occasionally with whitish yellow zones more or less extensive over the convex surface, due to perisplenitis. The organ was smooth on its surface and its consistency was generally increased and on section its substance was not diffluent and the structure of the organ could be seen. The liver was sometimes increased in size but otherwise was normal, and seldom showed signs of circumscribed perihepatitis The gall bladder was always full of dark green (occasionally almost black) bile there was no catarrh or other obstruction in the ducts. The kidneys sometimes showed signs of congestion and even of slight inflammation. There was no perinephritis the capsules being always easily detached. The abdominal lymphatic glands were generally congested.

Microscopic sections were cut chiefly from those parts of the surface of the brain over which the meninges were most thickened from the pons Varolii, medulla oblongata, and cervical dorsal and lumbar cord and from the upper vermiform process the corpus striatum and optic thalamus In general the infiltration of leucocytes in the meninges of the pia mater and arachnoid was intense, and more pronounced in the curves of the vessels of the pia mater and of those which penetrate into the nervous substance and the vascular walls were often found considerably thickened and surrounded by round cells in the white matter of the cerebrum and medulla oblongata. This infiltration was also remarkable in the grey matter of the centres and was more or less diffused or intense the round cells being accumulated in some cases round the nerve cells, above or near the great pyramids of the cerebellum where the form was not infrequently modified by the vicinage of three or four small round cells (with strongly coloured nuclei) which rested on them hollowing out a depression in the edges of the nerve-cell on which they were lodged Alterations of this character were observed in the sections of the paracentral lobe. These spherical cellular corpuscles were found scattered in the white matter but far less abundantly and disappeared altogether in the deep layers of certain cerebral regions. When in cases of long standing the inflammation spread to the dura mater adhesions were formed between it and the subjacent meninges and connective tissue of new formation but sufficiently vascularised was found this formed the composition of certain mulberry like productions which were met with on the upper border of the hemispheres Nothing certain and special could be found out about minute cytological changes Alongside cells which preserved the normal arrangement and aspect of the nucleus nucleolus and chromophil corpuscles of Nissl were seen other cells the outlines of which were always clear but the diffused colouration of the protoplasm did not permit the aforesaid granulations to be distinguished. In others again, these granules were decidedly reduced in size and their colouration did not show the intensity which it had in normal cells The general appearance of the majority of the nerve cells did not indicate grave lesions of those elements

The search for micro-organisms gave in one respect important results. The diplo-streptococcus existed in considerable quantities in the vessels of the pia mater in the cerebral and medullary capillaries, in the lymphatic sheaths of the vessels and also in the intra-cellular nerve-substance In a bronchial gland extracted from the same body there were numerous diplo-streptococci these were the only micro-organisms constantly disclosed by the investigations made ante and *post mortem* In the preparations made with the cephalo-rachidian fluid obtained by lumbar puncture with the juice of the engorged glands extracted during life or at the necropsy and with the meningeal exudation, micro-organisms were found arranging themselves in pairs more or less rounded, at times slightly elliptical, but in general hemispherical and with their flat sides facing one another, so that they resembled the coccus of Neisser and the diplococcus intracellularis meningitidis of Weichselbaum Almost always there was seen round them an aureola clear and thin but distinctly perceptible These forms of diplococci were commonly observed in the cephalo rachidian fluid and in the glands examined during life, but were then so rare that only two or three could be found on a slide by very careful examination In the meningeal exudation these diplococci were as a rule the only bacteria which could be observed, but occasionally in necropsies made 10 or 12 hours after death many of the diplococci were seen to be arranged in chains of two, four, eight, or sometimes more. In the exudations collected from fresh bodies the microbes were at first exclusively arranged in pairs, but after they had been kept from 20 to 24 hours in the stove at from 35° to 37° C they presented numerous diplo-streptococcic forms, evidently developed in the pathological product outside the organism. In most cases the micro-organisms were found free in the exudation, rarely some existed in the interior of the protoplasm and even in the nuclei, of the leucocytes, or in the endothelial cells of the coverings of the brain. They measured from 1 5μ to 2μ, each element measuring one-half of this The diplococci are generally much more frequent in the cerebral exudation than in the cephalo-rachidian fluid, but the proportions may be equal. They were easily coloured with different aniline dyes, they were not easily cultivated, but the fluid proposed by Martin for the cultivation of Löffler's bacillus and obtained by maceration of a pig's stomach, or still better a mixture of ascitic fluid and meat-broth in equal quantities, gave good results In the fluid medium containing peritoneal transudation, after from 18 to 24 hours at from 35° to 37° C, a slight development was shown by light and uniform turbidity, this turbidity increased steadily but never attained great intensity, at the end of four or five days there was a slight sediment of bacteria in the bottom of the receptacle and the liquid often became limpid. In the above solid medium there appeared very small colonies, rounded or oval, greyish white, fairly translucent, slightly salient and somewhat bright on the surface, their growth ceased on the third or fourth day, at which time they did not exceed from 0 2 millimetre to 0 3 millimetre, seen through the microscope under a low power they showed themselves at first to be composed of very tiny granulations and their contours were not very bright, later, two zones, one central and dark, the other peripheral and clearer, might easily be distinguished in them. Gelatin cultures were not successful This diplo-streptococcus had no great pathogenic effect on animals, if injected into the peritoneal cavity of guinea pigs or into the pectoral muscle of pigeons, even in large doses of fresh cultivations, no morbid symptoms appeared, but rabbits and mice were sensitive to it, in the former, subcutaneous injections were occasionally fatal, intravenous injections were more certain, for from one to two cubic centimetres of a cultivation 24 or 48 hours' old in liquid ascitic media caused death in a time varying from two to seven days, the micro-organisms inoculated being found in greater or less abundance in the blood and spleen. In mice doses of from 0 5 to one cubic centimetre of the culture or a few drops of the meningeal exudation injected under the skin caused death through septicæmia in from two to four days The spleens of the animals which died from this injection preserved normal dimensions and consistency, renal congestion in the rabbits which resisted the disease the longest was the only visible morbid change.

The investigations intended to clear up the etiology of the sleeping disease were made with the cephalo-rachidian fluid obtained by lumbar puncture, with lymphatic glands extracted during life or after death, with blood aspirated from the veins by a sterilised syringe, and with the meningeal exudation after death. Lumbar puncture was performed nine times and in six cases the above-described bacteria were found On three occasions glands were extracted during life and in two cases these bacteria were present The blood of four patients was examined, having been drawn off with a Debove's syringe after careful disinfection of the skin, in two cases there were no streptococci, in a third a diplo-streptococcus was found exactly answering to the above description, the fourth specimen was spoilt. In the meningeal exudation of the dead body this diplo-streptococcus was found in all the 13 cases which were examined These bacteria were named diplo streptococci because they resembled Fraenkel's diplococcus and also the streptococcus, and cannot be identified with either of these groups, which, however, are closely allied. Possibly this diplo streptococcus of the sleeping-disease may be a type of transition between Fraenkel's microbe and the streptococcus

The Commission came to the conclusion that the sleeping-disease when fully developed was a form of meningo-cephalitis and that treatment would be difficult, but might be possible in the early stages by medical remedies or surgical intervention It considered also that the isolation of the microbe might suggest a rational prophylaxis, but that the low state of civilisation of the patients and their ways of life and racial habits would make it difficult to insist on any suitable hygienic precautions in the native villages, but that in farms and industrial establishments such precautions could be more easily enforced

The report is dated from Loanda, August 10th, 1901.

The treatment of this disease in Lisbon was not very successful, for of 28 cases brought to that town by the Commission only five survived after 10 months and they were still suffering from the disease

Dr Patrick Manson says that this disease is confined to western equatorial Africa, between the valley of the Senegal on the north and that of the Congo on the south, and that it extends far into the interior of the continent, being especially prevalent in the districts of Baol and Sin on the coast of Senegambia and on the Lower Congo He adduces a case in which the disease was developed three years after removal from an infected district Natives say that it may appear after an interval of seven years Negroes over 40 years of age are exempt, but they seldom live so long One European, a Moor, and a mulatto are said to have suffered from this disease Dr Manson mentions among the symptoms of the disease enormous bed sores, choreiform movements in groups of muscles, spasm of the pharyngeal muscles rendering swallowing difficult, and rigidity of the sterno mastoid or of the extensors of the neck. He says that insanity is observed in 10 per cent of the cases from the Congo and that dulling of the sense of touch in limited patches or larger areas is often noticeable and that papulo-vesicular eruptions, especially over the front of the chest, and pustules on the face, as well as cutis anserina, were common symptoms On the authority of a missionary he mentions that the hair becomes lighter and reddish before the disease develops itself The natives believe that the saliva when thick and glutinous conveys infection. He found filaria perstans in six out of 10 cases He adduces theoretical reasons for ascribing the disease to a lesion of the pituitary gland Dr Manson says that hypodermic injections of testicular extract have been found efficacious and on lay authority that large doses of liquor arsenicalis may cure in the early stage.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE British Association met this year at Belfast from Sept 10th to 17th, under the presidency of Professor J DEWAR. The proceedings opened with the Presidential Address by Professor DEWAR, an abstract of which will be found in THE LANCET of Sept 13th, p 723 The scientific work of the association was carried on in 11 sections and the quality of the papers was well up to the standard of former years

The address in Physiology was given by Professor W D HALLIBURTON It will be found in THE LANCET of Sept. 20th, p 787

Dr W A. OSBORNE then read a paper on the Hydrolysis of Glycogen The researches were carried out with Mr S ZOBEL Glycogen when hydrolysed by a diastatic ferment gave rise to bodies very similar to those derived from starch Glycogen when acted upon by saliva gave rise to dextrine, maltose, and dextrose

Dr W PAGE MAY read a paper on the Innervation and Movements of the Stomach He showed that stimulation of any sensory nerve or mental excitement produced diminution or cessation of the movements of the stomach and that this was brought about through the vagi, which being stimulated produced first inhibition and then increase of the gastric movements. He showed that stimulation of the splanchnic nerves produced only spurious results and had *no direct* influence on the movements of the stomach or its muscular tone This result differed from those of previous observers

Dr F W EDRIDGE GREEN read a paper on the Functions of the Rods and Cones of the Retina. He claimed to have proved that the rods and cones had entirely different functions. He had found on examining the retinas of monkeys kept in a dark room for 24 hours previously to the excision of their eyes that the yellow spot, instead of being *free from* visual purple, was the reddest part of the whole retina. This purple was around, not in, the cones. He believed that light acting upon the retina liberated the visual purple from the rods and a photograph was formed the cones and optic nerve fibres conveying the impression to the brain According to this theory the cones were only sensitive to chemical changes in the visual purple and not to light itself.

Professor E A. SCHÄFER read a paper on the Diuretic Action of Pituitary Extracts. His experiments appeared to indicate that the diuretic action was not confined to extracts obtained from the infundibular part, but was also shown by extracts both watery and alcoholic, from the hypophyseal, that was, the epithelial part of the body It was interesting to learn from clinical observers that diuresis was sometimes a very marked symptom in acromegaly a disease associated with enlargement of the pituitary body and cases were sent to the hospital as diabetes.

Professor SCHÄFER then read another paper on the Relative Effects of Section of the Pyramidal Tracts and Anterior Columns in the Monkey Dr CECIL SHAW showed a rare case of Paralysis of Convergence probably of cerebral origin in a boy aged nine years Other papers read in this section were Dr C S. MYERS Determination of the Least Perceptible Tone Difference among the People of the Torres Straits and of Scotland. Dr J TURNER Some New Features in the Intimate Structure of the Cerebral Cortex. Dr PAGE MAY The Nervous System of the Camel Professor HALLIBURTON and Dr. F W MOTT Nerve Regeneration Mr J BARCROFT The Estimation of Urea in Physiological Fluids Professor J SYMINGTON and Dr CECIL SHAW A demonstration of Edinger's Apparatus for Higher Magnification and Stronger Light. Dr W A. OSBORNE The Pigments of Ox Bile. Professor F GOTCH The Indefatigability of Medullated Nerve

Professor D J CUNNINGHAM read a very interesting paper in the section for Anthropology on Cornelius Magrath, the Irish giant to which we refer elsewhere.

In the Geographical Section Mr J MILNE, F R S read a paper on World shaking Earthquakes. He showed how the position of the earthquake was localised. The results of his investigations showed that where there was the deepest water there were the worst earthquakes as, for instance, off the coast of Japan. In any part of the world, if they got an average slope of 1 in 20, they might look out for earthquakes, but where there was a gentle slope there were no earthquakes The cooling of the earth was going on every day and the result was that the outer portion folded and earthquakes occurred.

In the Mathematical and Physical Section a paper was read by Lord KELVIN on an Animal Thermostat and by Dr EDRIDGE-GREEN on the Physical Aspects of a Theory of Colour Vision.

The lectures were given by Professor J J THOMSON on Becquerel Rays and Radio-Activity and by Professor W F WELDON on Inheritance. Professor Weldon said that it was the business of a student of inheritance to find out how much they could infer about the characters of a group of animals or plants from a knowledge of their ancestry There were certain limits to the knowledge of animals or plants which they could obtain from a study of their ancestry but a study of ancestry alone neglected a whole class of circumstances on which the characters of an animal or plant depended. Every character of a living organism was determined partly by the constitution of the germ from which it was developed which contained characters transmitted to it from its ancestors, and partly by the conditions of the environment in which that development took place. Some very interesting illustrations of the effect of environment were shown, as, for instance the arrest of development of a spine in a certain species of daphnia when partially poisoned by its own excrement.

THE BELGIAN CONGRESS OF SURGERY

THIS Congress was opened on Monday morning Sept. 8th, at the Palais des Académies in Brussels. A reception was held on the previous evening at the Hôtel Métropole to welcome the foreign surgeons who had accepted the invitation of the organising committee and to introduce them to their Belgian *confreres*.

On Monday Dr CHARLES WILLEMS of Ghent, President of the Congress, supported by Dr KUFFERATH and Dr VAN HASSELL, Vice-Presidents, and Dr VERNEUIL, the general secretary pronounced the Congress open. After having thanked the foreign surgeons for leaving each his own country although science was a country common to them all, to be present at the meeting and having wished them a hearty welcome he proceeded to discuss the relations which existed between medicine and surgery at the present time Formerly Dr Willems said, it was admitted by everyone that the intervention of surgery was far less frequent than now The physician in the treatment of his cases awarded to surgery quite a *secondary* place Surgery moreover at that period held a position relatively unimportant compared to that which it occupied to-day As a matter of fact, the practice of medicine was now more fraught with peril than it was in former times, for since operative interference was able to succour so many patients who formerly had to be abandoned to their fate the physician ought to feel that a heavy responsibility rested upon him. He must be in no doubt, he must be alert, he must not remain impassive when the opportune moment arrived which would permit surgical interference to rescue from death a human being And the indications for operation were all important to him to know It had devolved upon the surgeon very largely at the present day to point out the way to the physician, although there were of the latter many who recognised with exactitude the indications for operation and who were on this account themselves surgeons although they did not wield the knife. But, nevertheless, speaking broadly medicine and surgery still were separated too widely and kept too distinct by reason chiefly of the methods by which they were taught. Each teacher isolated his course of instruction as if his subject were a separate entity—alongside others but not actually in contact with them. The influence of this method often had a deleterious effect upon a student throughout his life. The invasion of medical treatment by surgery which had taken place in so notable a degree within the last few decades clearly demonstrated after the great discoveries of Pasteur and Lister which inaugurated the development of modern surgery that a mission was imposed upon surgeons to popularise the idea of how vast importance might be the indications for surgical interference in the treatment of maladies in general.

The Congress then proceeded to the discussion of the subject for the day—that of the Treatment of Appendicitis Dr BROCA (Paris) in conjunction with Dr GALLET (Brussels) presented a paper dealing with their experience of the disease, strongly expressing a preference for operating wherever possible during a quiescent period and not during an acute attack. The paper that excited the greatest interest was that of Dr SONNENBERG of Berlin who gave the results of 1200 operations that he had performed within the last 12 years at the Moabit Hospital Berlin. He laid great stress upon the importance of observations upon the augmentation of the white blood corpuscles (leucocytosis) which bore a remarkable relation to the gravity of the lesions in appendicitis and to the reaction of the peritoneum. In many conditions leucocytosis afforded a diagnostic element of great importance more trustworthy than the pulse and temperature as an indication when to operate. Dr Sonnenberg with Dr Broca advocated operating during a quiescent period whenever possible.—Dr SOREL (Havre) took the opposite view advocating operative intervention within the first 12 or 24 hours.—In the afternoon the discussion was continued by other speakers.

Nearly 100 surgeons had assembled and almost every country in Europe was represented. In the evening the President and Madame Willems gave a musical soirée at the Hotel Mengelle where, under the influence of their genial hospitality a very enjoyable evening was spent.

On Tuesday morning the question under consideration was the Treatment of Fractures of the Limbs. Various methods of treatment were demonstrated, the principal speakers being Dr TUFFIER (Paris), Dr HANNECART (Brussels), and Dr ROTHSCHILD (Frankfort) —In the afternoon the Congress proceeded to discuss the project of the foundation of an International Society of Surgery In setting forth this project Dr WILLEMS, after referring in appropriate terms to the late illustrious Virchow, pointed out the need and utility of such a society formed exclusively of those practising surgery It would have for its work the study of some of those great questions which could only be adequately advanced by the harmonious concurrence of many workers, such as the study of new operative measures in the treatment of cancer for example This proposal was approved by Dr Sonnenberg, Dr Berger, and others, and the principle of the foundation of such an international society of surgery was adopted with unanimity A provisional committee was thus constituted Dr Broca (France), Dr Sonnenberg (Germany), Mr Reginald Harrison (England), Mr Macewen (Scotland), Dr Gussembauer (Austria), Dr Dollinger (Hungary), Dr Giordano (Italy), Dr Jacques Reverdin (Switzerland), Dr de Isla (Spain), Dr Bloch (Denmark), Dr Roswell Park (United States), Dr C Willems (Belgium), Dr Djemil Pacha (Turkey), and Dr Welliaminoff (Russia), &c

The members of the Congress dined together at the Restaurant de la Monnaie in the evening with Dr Willems in the chair, and a very pleasant evening was passed, great cordiality prevailing

Wednesday morning was given up to the discussion of Asepsis and Antisepsis in Relation to Operations, after which the President declared the session closed.

THE ETIOLOGY AND PROPHYLAXIS OF ENTERIC FEVER IN ARMIES ON FIELD SERVICE

THE author of a recently published German work[1] on this important subject sums up his views as follows —

1. During the last 40 years the most frequently observed and most widespread epidemic manifestation in time of war has been typhoid fever

2. Typhoid fever is due to the bacillus of Eberth, which was cultivated in a pure state for the first time by Gaffky, and of which the specific nature was demonstrated by the reaction of Pfeiffer, the method of Widal, and the possibility of obtaining the immunisation of the human organism by sterilised cultures.

3 It is principally in the human body that the bacilli of Eberth find their field of growth , they leave it either with the intestinal evacuations or in the urine

4 The transmission of the affection often takes place through association with patients , it occurs notably amongst those who give their services to them. The contagion also attaches itself to linen, clothing, and the articles provided for the use of the patients.

5 Epidemics of typhoid fever originate for the most part in consequence of the transmission to a large number of persons of the bacilli derived from patients affected with the disease The propagation of the germ is most frequently accomplished by means of water , sometimes also by means of food which has been soiled by the dejections of the patient. The germs of the affection are also capable of being contracted in the dwellings and in the latrines that have been frequented by patients The contamination of the surface of the ground contributes likewise to the spread of the disease

6 The outbreak of epidemics of typhoid fever is favoured by default in local hygienic measures

7 The young are particularly predisposed to contract the disease. An organism healthy and vigorous, hardened by exercise, possesses nevertheless the power of resistance in a marked degree

8 Epidemics of typhoid fever among armies in the field have often had as point of departure the manifestation of a few cases of the disease which were already implanted among the troops before the war, or which may have shown themselves among the detachments destined for reinforcement during the campaign

9 In consequence of the great prevalence of typhoid fever among civil populations, armies in the field are as much exposed to the contagion in their own country as in that of the enemy

10 An army in the field becomes liable to contagion from the moment that the disease makes its appearance among the enemy The contagion operates chiefly through the occupation of camps and cantonments which have been abandoned by them and also by means of the prisoners of war

11. The dissemination of the imported disease is favoured in armies on service by the concentration of troops, by over fatigue, and by insufficient nourishment, as well as by the difficulty, sometimes the impossibility, of applying the rules of general hygiene, including the measures of special prophylaxis suitable during an epidemic

12 The struggle against the disease is nowadays rendered more easy by the greater knowledge of its mode of extension that is being acquired

13 In order to protect troops in the field in an efficacious manner against epidemics of typhoid fever, it is of the first importance that fractions of already infected corps should not be allowed to enter into the composition of the army , and that bodies of men with sickness among them, or even suspected thereof, should not be incorporated with the troops in reserve. It becomes more easy to eliminate such dangerous elements when it is known that typhoid fever is prevalent in the localities whence they are derived.

14 For this reason, and also to prevent the introduction of germs from the civil population into the place where mobilisation is being carried out, it is necessary that the superior military authority should be informed, even in time of peace, regarding the localities where typhoid fever exists

15 When war breaks out military medical officers specially trained in questions of hygiene should be sent in advance to the place where the concentration of the troops is to be carried on It should be the duty of these officers to come to an understanding with local authorities, and also with the medical men practising in the district, in order that they may discover centres of typhoid fever and if possible render them innocuous When the troops arrive these officers should act in concert with the military authorities, as well as with the medical officers accompanying the various sections

16 On arrival in an enemy's country it is the duty of medical officers to inform themselves regarding the hygienic condition of the localities where camps are established, and to communicate their information to the military authorities who in their turn should communicate any important details that may have come to their knowledge

17 All communication between the troops and civilian patients suffering from typhoid fever should be avoided The sources of water supply which are susceptible of contamination should be guarded , and in like manner the use of all articles of food which have been exposed to the risk of soiling should be interdicted It is necessary to take every precaution in order that the contagion emanating from patients should not be spread abroad out of doors

18 Prisoners of war should be removed as soon as possible from the districts occupied by an army in the field The sufferers from typhoid fever among the prisoners of war should be treated in the same manner as those belonging to the army

19 The best protection against such germs of the disease as may have escaped immunisation on dispersal is a strict observance of the rules of hygiene

20 Cantonments, camps, and bivouacs should not be overcrowded a strict supervision of cleanliness, especially as regards the removal of night-soil, is essential.

21. Drinking water should only be taken from sources which are entirely free from suspicion If such sources are unattainable it is permissible to attempt purification from suspected germs by means of Chamberland or Berkefeld filters The simplest and most certain means is boiling In order to supply potable water in large quantity sterilisers on wheels might advantageously be used As soon as time and labour are available all existing water-sources should be improved and new ones of an irreproachable character established

22. Food supplies should be suitably protected from contamination kitchens should be adapted for cleanly cooking, which is a safeguard against noxious germs

---

[1] Entstehung Verhütung und Bekämpfung des Typhus bei den im Felde stehenden Armeen Berlin: A. Hirschwald 1901 Pp 110.

23. As far as possible the troops should be saved from overwork and from intemperance.

24 In order that the struggle against typhoid fever in the army may be carried on it is necessary to search out any early cases of the disease and as far as possible to trace the contagion from them

25. Even in suspected cases isolation should be enforced and all measures adopted for the preservation of the hospital *personnel* Removal of the patients should be enjoined if possible they should be sent to the rear to isolation hospitals far from the theatre of operations

26. Troops which have occupied a cantonment where there have been cases of typhoid fever or which have been in more direct contact with them, should be isolated and placed under medical supervision until all risk of contagion has passed. In certain cases it may be permissible to inoculate a threatened corps against typhoid fever, as soon, that is, as a sure and practical method of immunisation shall have given practical proofs of its worth.

27 When a patient leaves a cantonment his clothes and and all articles made use of by him should be submitted to disinfection

28 Commanding officers should immediately be informed of the appearance of typhoid fever among the troops in order that they may assist the medical officers in their contest with the malady and prevent its extension among the other sections of the army

29 The same authorities should have at their disposal military medical officers who have been trained in practical hygiene and bacteriology and who are provided with all necessary means for conducting technical research. These medical officers should be especially instructed to seek out the points of penetration of the epidemic affection to superintend and to make technical examinations, and to prepare and to superintend prophylactic measures. It should be permissible to send them to threatened places in order that they may take part personally in the struggle against the disease

30 In order to fight successfully against typhoid fever in the field it is essential that practice should take place in time of peace with the same means and on the same scale as in war time.

Looking Back.

FROM

THE LANCET, *SATURDAY, SEPT* 25, 1824

Case of a young woman who has discharged and continues to discharge from her stomach, a number of Insects By WILLIAM PICKELLS, M B one of the Physicians to the Cork Dispensary &c.

This very extraordinary case is recorded in the last volume of the *Transactions of the Association of Fellows and Licentiates of the King and Queen s College of Physicians in Ireland* a very meritorious, valuable and spirited work and of which we shall take farther notice in some of our future numbers.

The subject of this singular case is Mary Riordan aged 28 years she is of marked sensibility and melancholic temperament, or she may be described as labouring under religious melancholy As the patient is still living and as her horrible affliction has not terminated we shall defer giving the whole of Dr Pickells detail to another opportunity – our present extracts however will be more than sufficient to point out to our readers the nature of this young woman s most appalling malady The first discharge of insects took place on the 22d of April 1822, and was preceded by a flow of blood from the mouth nose, and ears. The various insects which have been at different periods ejected from April 1822 to 1823, have been represented in the plates which accompany these *Transactions* Dr Pickells says

Of the larvæ of the beetle, *I am sure I considerably underrate* when I say that, independently of above a hundred evacuated *per annum* not less than *seven hundred* have been thrown up from the stomach at different times since the commencement of my attendance. My own reckoning during my personal attendance, gives upward of four hundred but in this calculation is not included the number thrown up during my absence of three months, a period marked by the expulsion from the stomach of such larvæ, almost daily in some instances, as reported to the amount of above thirty at a time. A great proportion were destroyed, from an anxiety to evade publicity Many too escaped immediately after having been vomited, by extricating themselves quickly from the vessel, and running into holes in the floor

Upwards of ninety were submitted to Dr Thompson s examination nearly all of which including two of the specimens of tenebrio molitor I saw myself thrown up at different times. The average size was about an inch many however, which I measured were an inch and a half in length, and four lines and a half in girth.

The larvæ of the dipterous insect, though voided only about seven or eight times, according to her account, came up almost literally in myriads. They were alive and moving None of those have been known to have been discharged within the last seven months.

The larvæ of the beetle were with few exceptions lively and vigorous in the extreme nor was it possible, without a feeling of horror to view them frisking along the bottom of the vessel in which they were preserved, occasionally expanding their jaws, and extending their denticulated feet or talons as their unfortunate victim used to call them. Some, which were apparently dead, revived upon exposure to heat

‘ Enclosed in empty pill boxes several lived upwards of a month. Mr Clear of this city has succeeded in preserving some of the earliest thrown up still alive, now after an interval of a year by keeping them in little pots filled with clay and so secured as not to exclude the air Some specimens of the larvæ of blaps, which I gave to Mr Clear when kept in flour were observed to be continually running to the surface as if impatient of their situation, and seemed not to thrive but when placed in clay, quickly buried themselves, and seemed to enjoy their native element." 209

Dr Pickells having been desirous to ascertain by what mode these insects or their ova, were introduced into the stomach the patient, in reply to his interrogatories stated, that

When she was about fifteen years of age, it appears that two much respected clergymen of her persuasion having died she was told by some old women that if she would drink daily during a certain period of time, a portion of water imbued with clay, taken from the graves of these clergymen she would be secured for ever against both disease and sin She accordingly walked to Kinsale, a distance of twelve miles, where one of the clergymen was interred and succeeded in bringing away an apron and pocket-handkerchief full of clay from his grave. To this she added, upon her return a handkerchief and some mugs full of clay obtained from the grave of the other clergyman, who was buried in this city Her practice was, to infuse water from time to time, according to the exigency in a vessel containing a proportion of clay so collected the mixture having been always allowed to rest until the grosser particles of clay fell to the bottom." 212.

We would, in conclusion merely hint to Dr PICKELLS, the necessity which often exists of taking particular care to guard against imposition It appears to us to be required in the present instance.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8914 births and 5053 deaths were registered during the week ending Sept. 20th. The annual rate of mortality in these towns, which had been 15 9 and 16 4 per 1000 in the two preceding weeks further rose to 17 7 per 1000 last week. In London the death rate was 17 3 per 1000, while it averaged 17 9 in the 75 other large towns. The lowest death rates in these towns were 5 5 in Hornsey 5 6 in Handsworth, 6 8 in Bournemouth, 8 0 in West Hartlepool, 9 2 in Burton upon Trent, 9 3 in Wolverhampton, 9 5 in Coventry and 9 8 in Croydon the highest rates were 22 6 in Stockport, 23 4 in Manchester 23 7 in Salford 24 1 in Birkenhead 24 3 in Great Yarmouth 25 5 in St. Helens, 25 7 in Middlesbrough and 26 0 in Liverpool The 5053 deaths in these towns last week included 1188 which were referred to the principal infectious diseases, against 743, 895, and 1062 in the three preceding weeks of these 1188 deaths 868 resulted from diarrhœa, 75 from whooping-cough, 72 from measles, 64 from "fever" (principally enteric), 54 from diphtheria, 52 from scarlet fever, and three from small-pox. No death from any of these diseases was registered in Bournemouth, Burton-upon Trent, Coventry, West Hartlepool, and Tynemouth, while they caused the highest death rates in Nottingham, Leeds, Liverpool, Cardiff, Middlesbrough, West Ham, Preston, Wigan, and Birkenhead The greatest proportional mortality from measles occurred in Reading, Birkenhead, and Newcastle upon Tyne, from scarlet fever in West Bromwich, from diphtheria in Bury, from whooping-cough in Cardiff and Huddersfield, and from diarrhœa in Middlesbrough, Birkenhead, Wigan, and Preston. The mortality from "fever" did not show a marked excess in any of the towns Three fatal cases of small pox were registered in London, but not one in any other of the 76 large towns. The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been 109 95, and 71 at the end of the three preceding weeks further declined to 47 at the end of last week, four new cases were admitted during the week, against 11, 12, and seven in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2651, 2713, and 2669 on the three preceding Saturdays, further declined to 2657 on Saturday, Sept 20th, 309 new cases were admitted during the week, against 295, 333, and 311 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 139, 123, and 134 in the three preceding weeks, further rose last week to 139, but were 27 below the corrected average number The causes of 50, or 1 0 per cent, of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Portsmouth, Bristol, Leicester, Nottingham, Bolton, Bradford, Leeds, Newcastle upon Tyne, and in 46 other smaller towns, the largest proportions of uncertified deaths were registered in Bootle, Ipswich, Warrington, and Stockton upon Tees

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 14 0, 13 9, and 14 8 per 1000 in the three preceding weeks, fell again to 14 1 per 1000 during the week ending Sept 20th, and was 3 6 per 1000 below the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 12 5 in Perth and in Aberdeen and 13 7 in Edinburgh to 15 1 in Greenock, 15 4 in Paisley, and 15 9 in Leith The 456 deaths in these towns included 21 which resulted from diarrhœa, 10 from whooping cough, four from "fever," three from diphtheria and from measles, and two from scarlet fever In all, 43 deaths were referred to the principal infectious diseases last week, against 45, 54, and 52 in the three preceding weeks These 43 deaths were equal to an annual rate of 1 3 per 1000, which was 2 9 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 14, 31, and 21 in the three preceding weeks, were again 21 last week, of which 11 occurred in Glasgow The deaths from whooping-cough, which had been eight and seven in the two preceding weeks, rose again to 10 last week, and included four in Glasgow The fatal cases of measles, which had been four, six, and seven in the three preceding weeks, declined again to three, two of which occurred in Edinburgh The deaths from "fever" numbered four, and included two in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 54, 61, and 82 in the three preceding weeks, declined again to 57 last week, and were 24 below the number recorded in the corresponding period of last year The cause of one death (registered in Aberdeen) was not certified either by a registered medical practitioner or by a coroner

HEALTH OF DUBLIN.

The death rate in Dublin, which had been 22 7 and 19 1 per 1000 in the two preceding weeks, rose again to 22 3 per 1000 during the week ending Sept. 20th. During the past four weeks the death rate has averaged 21 2 per 1000, the rates during the same period being 16 7 in London and 13 6 in Edinburgh The 162 deaths of persons belonging to Dublin registered during the week under notice included 41 which were referred to the principal infectious diseases, against 28 and 30 in the two preceding weeks, of these 20 resulted from diarrhœa, 13 from measles, four from diphtheria, two from scarlet fever, and one each from whooping cough and from "fever," but not one from small pox. These 41 deaths were equal to an annual rate of 5 6 per 1000, the death-rates last week from the same diseases being 3 9 in London and 1 3 in Edinburgh The fatal cases of measles, which had been 11, 10, and six in the three preceding weeks, rose again last week to 13. The deaths from diarrhœa, which had been seven, 10, and 19 in the three preceding weeks, further rose to 20 last week. The deaths from "fever," which had been three in each of the two preceding weeks, declined to one last week. The 162 deaths in Dublin included 51 of children under one year of age and 27 of persons aged upwards of 60 years, the deaths of children and of elderly persons both showed a slight increase as compared with the numbers in the preceding week. Three inquest cases and one death from violence were registered, and 63, or nearly two fifths, of the deaths occurred in public institutions The causes of four, or 2 5 per cent, of the deaths registered in Dublin were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified —Fleet Surgeon W M Lory to the *Unicorn* Staff Surgeons Robert Hardie to the *President* for three months' course of hospital study Frederick Fedarb to the *Intrepid* on commissioning, Henry J Hadden to the *Empress of India*, John H. Whelan to the *Resolution*, and R T A Levinge to the *Pyramid* Surgeons Thomas B Shaw to the *Empress of India*, Robert W Hall to the *Resolution*, William E. Ruttlege to the *Grasshopper*, and W G Westcott to the *Northampton* for the *Calliope*

ROYAL ARMY MEDICAL CORPS.

Major M. W H. Russell is appointed to the Home District for duty at the War Office. Lieutenant-Colonel R. J Fayle has joined at Pembroke Dock for duty, vice Lieutenant-Colonel H. Hathaway, who shortly embarks for service in India Major R. J Anderson Durant is appointed for duty in the Western District

Robert Joseph Franklin to be Lieutenant on probation, vice G T Collins, deceased Dated Sept 1st, 1902, but not to carry pay prior to Sept 6th, 1902

INDIA AND THE INDIAN MEDICAL SERVICE.

Surgeon Major General P S Turnbull, retired, to be Honorary Surgeon to His Majesty, vice Surgeon General S W Hunter, K C M.G, deceased Dated Sept 20th, 1902

IMPERIAL YEOMANRY

The undermentioned officer resigns his commission and receives a new commission subject to the provisions of the Militia and Yeomanry Act, 1901, retaining his present rank and seniority, viz. —

Fifeshire and Forfarshire Surgeon-Lieutenant Macdonald

VOLUNTEER CORPS

Royal Garrison Artillery (Volunteers) 1st Aberdenshire Surgeon-Lieutenant W A. Macnaughton to be Surgeon-Captain 1st Edinburgh (City) Surgeon Major G R. Gilruth resigns his commission, and is granted the rank of Surgeon Lieutenant-Colonel, with permission to wear the uniform of the corps on retirement 1st Cumberland Surgeon Captain J H Dickson to be Surgeon Major

Rifle 3rd Volunteer Battalion the Queen's (Royal West Surrey Regiment), Surgeon Captain R J M Coffin to be Surgeon-Major 6th Volunteer Battalion the King's (Liverpool Regiment) The undermentioned Surgeon Captains to be Surgeon-Majors —J W Ellis and E W Barnes 2nd Volunteer Battalion the Lincolnshire Regiment Surgeon Captain H P Berry to be Surgeon Major 1st Volunteer Battalion, the Royal Scots Fusiliers Surgeon Lieutenant W M Boyd resigns his commission 1st Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment) Surgeon Captain E Vaudrey to be Surgeon Major 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment Surgeon Captain E. Evans to be Surgeon-Major

The undermentioned Surgeon Lieutenants to be Surgeon Captains —L. R. Williams and P A Lloyd. 2nd Volunteer Battalion the King's (Shropshire Light Infantry) Surgeon Lieutenant O E. Baddeley resigns his commission with permission to retain his rank and to wear the uniform of the battalion on retirement. 1st Volunteer Battalion the Durham Light Infantry Surgeon Major J W Blandford to be Surgeon Lieutenant-Colonel. 5th (Deeside Highland) Volunteer Battalion the Gordon Highlanders Surgeon Lieutenant W G Mitchell to be Surgeon Captain

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY

South Yorkshire Surgeon-Captain D G Newton, from 1st Volunteer Battalion the York and Lancaster Regiment, to be Surgeon Captain.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

Glasgow Companies Captain C C Fleming D S.O R.A.M C to be Adjutant, on increase of establishment.

THE GORDON HIGHLANDERS MEMORIAL INSTITUTE AT ABERDEEN AND SIR GEORGE WHITE.

On the occasion of Sir George White's opening the Gordon Highlanders' Memorial Institute at Aberdeen the late defender of Ladysmith it will be remembered, dwelt upon the advantages arising from habits of temperance in the army and the need that existed for the provision of places where the soldier could enjoy social intercourse without having to manifest his good fellowship by indulgence in alcoholic drinks It is not, as he was careful to point out, that the soldier is a more intemperate man than the civilian, for it is probable that the contrary is the fact, but he is much more exposed to temptation in that respect, especially on returning to this country at the end of a war General White also seized the opportunity of alluding in a few graphic touches to the conspicuous part which the Gordon Highlanders had played in the late war With regard to Sir George White himself we may say that throughout his army career he has always studiously regarded the soldier's health and interest. In whatever light the future military historian may be disposed to view the "entanglement" of Ladysmith the fact cannot be overlooked that the siege of that place had a disastrous effect on Boer strategy When the complete history of the late war comes to be written and the characters and work of the men engaged in it have to be weighed and judged, we venture to prophesy that Sir George White will stand out conspicuously for high mindedness. He disarmed criticism by chivalrously accepting responsibility he knew when to maintain a dignified reserve, and in all that he has said and done he appears to have been careful to think and to speak of others and not of himself.

THE MEDICAL EXAMINATION OF CANDIDATES FOR ARMY COMMISSIONS.

The *Army and Navy Gazette* of Sept. 20th in a paragraph referring to the medical and physical examination of candidates for Woolwich and Sandhurst makes some pertinent and useful remarks To begin with attention is called to the absolute necessity which exists for the parents and guardians of intending candidates to make themselves acquainted beforehand with the published regulations on the subject. In order to prevent much trouble and disappointment to all concerned it should obviously be ascertained in the first place whether a candidate fulfils, or is likely to fulfil, the requirements laid down These are set forth with quite sufficient clearness in the regulations to enable medical practitioners to give an opinion on the subject. The duty of the medical officers constituting the army medical board when it finally comes to them to decide as to the fitness or otherwise of any candidate has, of course, to be guided by the official instructions issued for their information—in fact for the information of all concerned. Of late—and probably in order to meet any complaints and to shift the responsibility of having to settle them—a "board of appeal" for rejected candidates for the army has been appointed to which our service contemporary objects on the ground that no such system obtains in the case of the Admiralty or the India Office The appeal board consists we believe, of the Director General of the Army Medical Service (as president) a retired medical officer with army experience, and a well-known ophthalmic surgeon.

THE TRANSPORT SCANDAL

It will be remembered that a commission was appointed to inquire into the alleged overcrowding of transports conveying colonial troops from South Africa. It is only right to state that the practical result of the investigation is reported to be in vindication of the Imperial Government authorities. The sickness and deaths on these transports were not caused by overcrowding but were, broadly speaking attributable to laxity of discipline and neglect of sanitary arrangements and personal hygiene on the part of the comparatively untrained troops on board.

THE INCREASED PAY OF MEDICAL OFFICERS SERVING IN INDIA

The *Pioneer Mail* of Sept. 5th says that until the Secretary of State's despatch sanctioning increased pay and charge pay for junior officers of the Royal Army Medical Corps has been received no formal action can be taken in regard to the Indian Medical Service. But it is practically certain our Indian contemporary adds that whatever concessions are granted to officers of the British Medical Service will be subsequently extended by the Government of India to officers of the Indian Medical Service.

STUDY FEES FOR NAVAL MEDICAL OFFICERS.

The fees (not exceeding £25) of the naval medical officers who undergo a three months course of study at metropolitan hospitals are now paid by the Admiralty in addition to travelling expenses, with lodging and provision allowances according to scale.

PRESENTATION TO MR. F M. FARMER, L.D S.

Surgeon-General Sir William Taylor K.C B. Director General of the Army Medical Service, has, on behalf of Mr Brodrick, presented to Mr Francis M. Farmer L.D S. R.C S. Eng a silver tea and coffee service in recognition of the valuable dental services rendered by him in South Africa during the late war

DEATHS IN THE SERVICES

Lieutenant George Berkeley Butt, I.M.S. in his twenty fifth year at Malakand, Frontier Provinces, India, on August 28th.

H.M S. *Terrible* which arrived at Plymouth on Sept. 16th had on board Surgeon C C Macmillan D S O R.N Staff Surgeon E. C Lomas, D S O R.N left the *Terrible* about 18 months ago and is now serving on the Mediterranean station.

Correspondence.

"Audi alteram partem."

THE VACCINATION CONTROVERSY

To the Editors of THE LANCET

SIRS,—The profession can ill afford to neglect public opinion on this subject, and I therefore ask you to publish the following remarks on it.

There is no more frequently repeated argument in the lay press than the following which I extract from a daily paper — "The fact that before vaccination was introduced the average small pox fatality rate amongst a wholly unvaccinated population was only 16 to 18 per cent. shows clearly that there must be other causes for the higher mortality in the unvaccinated, and that the want of vaccination has nothing whatever to do with it." This argument is constantly appearing in the papers in one form or another and I wish to draw attention to the untrustworthiness of this calculation which depends entirely on the correctness of the statistics of the eighteenth century Chicken pox was for the first time fully described in England in 1766, and my contention is that all calculations made previously to that date are rendered almost valueless from the necessary confusion between this disease and small pox. If the two diseases are classed together it is clear that supposing them equally prevalent, we should get a mortality little more than half that of small pox alone.

It is surprising that in the report of the Royal Commission there is no reference to this possible source of error although Bernouilli who wrote in 1760-65, is quoted, and his calculations are treated as if they were based upon reliable data. The fatality assumed by him was about 16 5 per cent and it seems highly probable that half the cases upon which this supposition was founded were chicken pox. This consideration alone appears to me to be sufficient to explain the discrepancy between the calculations of the eighteenth century and those of the present day

Again, we find in the report of the dissentients among the Commissioners that "the view that second attacks of small-pox occurred was held by Sydenham, also by Diemerbroek, who observed that the eruption was more severe in second attacks than the first. The case of Louis XV has been often quoted, he had a first attack at 14, and died of a second attack at 64" (§ 14) I ask what evidence is there to show that these so-called first attacks were not merely chicken pox? The observation of Sydenham that they were mild is very significant and it seems strange that Sir William Collins and Mr J A Picton should attach importance to such statements

Turning to the statistics of the present day, I would advocate a different method of presenting the facts in drawing up tables of statistics instead of the clumsy way often followed at present, in which those who have been vaccinated six months are often classed with those who have not been vaccinated for 60 years

The interests of truth do not require us to hide as much as possible the real meaning of the figures, and it is significant that anti-vaccinationists almost invariably ignore the lapse of time between vaccination and a subsequent attack of small pox. To give an example from a daily paper —"It is of the utmost importance to note that Dr Priestley admits that out of a total of 404 cases 325 were vaccinated Could there be a stronger indictment of vaccination?" How many readers of this will stop to inquire whether the 20 per cent of the cases who thus appear to have been unvaccinated correctly represent the unvaccinated proportion of the population? The figures as given have absolutely no significance to those who do not know the percentage of the population generally who are unvaccinated. The method I suggest for presenting the facts to the public should be somewhat as follows All persons to be divided into three classes thus (1) the protected—viz., those who have been vaccinated within 10 years, (2) the half protected, who have been vaccinated between 10 and 20 years, and (3) the unprotected, who have not been vaccinated within 20 years. We should then have results presented to us as follows, taking a table of statistics covering the first 1015 deaths of the present epidemic and excluding doubtful cases Deaths from small-pox among (1) the protected, one (certified to have been imperfectly vaccinated), (2) the half protected—between 19 and 26 (I am unable to give the exact number as I cannot get at the facts, although the table I am employing is to all appearances a very elaborate one), and (3) the unprotected, 905

I submit that such a method of presenting the facts is much simpler than those usually adopted at present, and better adapted to make popular the real meaning of the figures we have to deal with

I am, Sirs, yours faithfully,
Tollington park, N, Sept 20th, 1902. C E SCUDAMORE.

THE IMPUDENCE OF CERTAIN ADVERTISING DRUGGISTS

To the Editors of THE LANCET

SIRS,—I read in THE LANCET of Sept. 20th (p 836) the comment made by Sir William H. Broadbent upon a certain advertisement appearing in the *Medical Bulletin*, of which I am the editor, in Philadelphia, U S A. In answer to the criticism I would say that in the advertising pages of the *Medical Bulletin*, and, in truth in all medical publications in the United States of America, the editors of the journals are in no way responsible for the advertisements sent in by advertisers of preparations, drugs, or other material that have been accepted as legitimate, or that come within the scope of medical ethics I can assure Sir William Broadbent, as well as your readers, that the *Medical Bulletin* and its editor appreciate most thoroughly the facts set forth by him of the unauthorised use of his name and his endorsement of the preparation referred to in his letter

Just as soon as I return home after my holiday in England is over, where I take pleasure in coming every year to see your great hospitals and your medical and surgical development, I will see that the unauthorised use of Sir William Broadbent's name is corrected. It is too frequently the case that advertisers on both sides of the Atlantic use without authority the names and endorsements of distinguished professional men, thus misleading the readers of medical journals Every journalist will be only too glad to correct any unauthorised use of a physician's name in his journal

Yours respectfully,
JOHN V SHOEMAKER.
De Keyser's Royal Hotel London, E C,
Sept 22nd 1902.

A PLEA FOR THE MORE FREQUENT USE OF CHLOROFORM IN LABOUR

To the Editors of THE LANCET

SIRS,—As a general practitioner one is much interested in Dr T W Parkinson's letter in THE LANCET of Sept. 20th (p 835) concerning the administration of $CHCl_3$ in labour and one thoroughly endorses all contained in his letter As, however, one is often from unpreventable circumstances singlehanded while attending cases of labour the mode of the administration of the chloroform becomes a matter of prime importance. As it is impossible in these cases to be at the patient's head attending to the $CHCl_3$ and at the same time following carefully the course of the labour one is often obliged to allow the patient to give herself the anæsthetic. I consider the following one of the safest ways of giving $CHCl_3$ in these cases It is the method suggested by Mr W J Image of Bury St. Edmunds, and quoted in Sir Lauder Brunton's text-book of "Pharmacology, Materia Medica, and Therapeutics" in order to produce first stages of the action of anæsthetics Get an ordinary tumbler and put in the bottom of it some absorbent cotton wool, on this put a few drops of $CHCl_3$ and give to the patient to put over her nose and mouth to inhale while the pains are on, between the pains she should place the tumbler inverted on the bed The tumbler does not fit accurately over the face so that free access for admixture of air is allowed. If the patient holds the tumbler in her own hand she will not put herself too deeply under the influence of the anæsthetic as she will drop the tumbler before that effort is produced, but she will be able to give herself quite sufficient to dull sensation without dropping the tumbler This useful method does not appear to be widely known amongst general practitioners, hence my reason for calling attention to it.

I am, Sirs, yours faithfully,
T M CALLENDER, M D, C M Edin.,
Late Resident Surgeon Royal Maternity Hospital,
Sidcup, Sept 22nd, 1902 Edinburgh

DEATH FROM THE BURSTING OF A TONSILLAR ABSCESS

To the Editors of THE LANCET

SIRS —Mr Alexander Lyons[1] has drawn attention to a comparatively rare accident in cases of quinsy—viz, the bursting of the abscess with discharge of the pus into the larynx, causing death from suffocation Almost all the writers on diseases of the throat mention the possibility of this occurring and a few cases are scattered about in medical literature. There is one, for example, in Sajous's "Annual of the Universal Medical Sciences," 1889, vol. iv, E 13 I examined for my colleague, the late Dr Sturges, a young woman suffering from quinsy who died suddenly the following night, and at the necropsy the larynx was found to be full of pus In most of the fatal cases the abscess was ruptured during sleep The risk of this accident occurring emphasises the importance of incising the tonsil in cases of suppurative tonsillitis

I am, Sirs, yours faithfully,
F DE HAVILLAND HALL, M.D Lond
Wimpole-street, W Sept. 22nd 1902.

THE ELECTION OF A DIRECT REPRESENTATIVE TO THE GENERAL MEDICAL COUNCIL

To the Editors of THE LANCET

SIRS,—Your anonymous correspondent, "F R C S," need not distress himself as to the members of the Incorporated Medical Practitioners' Association being kept in ignorance of important facts relating to the nomination of Mr Joseph Smith as a candidate for election to the General Medical Council. They have been kept fully informed of every fact in connexion therewith. Mr Smith was not adopted officially as the candidate of the association and any members of our association who have supported him have done so only in their individual capacity The funds of the association have not been used to promote his candidature, so F R.C.S." may rest his soul in peace on that score Every member of the association has had full liberty of action to support either Sir Victor Horsley or Mr Smith. With regard to the personality and professional position of Mr Smith and of myself I am not disposed to discuss these with one who conceals his own personality under a *nom de plume* —I am, Sirs yours faithfully

---

[1] THE LANCET Sept. 20th, 1902, p 812

GEORGE BROWN

Hon Sec. Incorporated Medical Practitioners' Association.

Gibson-square N., Sept. 24th, 1902.

P S —What does F R.C S." mean by his reference to Mr Smith causing the profession the expense of a contested election? The expenses are paid by the General Medical Council with the exception of the personal expenses of the candidates.—G B

THREADWORMS AND APPENDICITIS

To the Editors of THE LANCET

SIRS,—Referring to the correspondence which has appeared in your columns on the above subject, it may be of interest to report that about three months ago I removed an appendix from a youth which contained two threadworms, both females and both full of eggs so that in all probability the appendix would soon have been crammed with threadworms as in the case related by Mr J Hutchinson, jun. The appendix was a particularly long one and its tip was fixed in the pelvis

I am Sirs, yours faithfully

J LIONEL STRETTON

Senior Surgeon Kidderminster Infirmary and Children's Hospital.

Kidderminster Sept. 21st, 1902.

THE BATTLE OF THE CLUBS

(FROM OUR SPECIAL COMMISSIONER.)

The Dispute at Chesterfield —Action of the Midland Medical Union.—A Minimum Rate for Contract Work.—United Front of the Medical Profession.—The Points at Issue

THE Midland Medical Union is at present involved in a struggle that interests the whole profession and it is necessary that the main points at issue should be as promptly and as widely known as possible. Some two years ago the medical practitioners in the neighbourhood of Mansfield and of Chesterfield began to hold meetings and to organise. There already existed a medical union at Nottingham and ultimately a general amalgamation was brought about, comprising the counties of Derby and Nottingham under the title of The Midland Medical Union. Mr J G Shea of Chesterfield was elected president. In his district the club or contract work was conducted in anything but a satisfactory manner Most of the clubs paid only 3*s* a year per member to their medical officers, while outside the town there were some clubs that did not pay more than 2*s* 6*d*. per member As soon as the Midland Medical Union was formed it was determined that an effort should be made to raise the subscription for medical attendance to 5*s* a year Considering the great increase in the cost of medical education and of medicines, and that unqualified assistants could no longer be employed, this demand was moderate enough and some of the better clubs at once assented to these terms. Nevertheless in regard to the generality of the clubs it represented too large an increase and after some negotiations the medical practitioners realised that it was not practical to enforce its general application Therefore on second thoughts they decided to content themselves with a uniform demand of a minimum of 4*s* a year There are 14 practitioners in Chesterfield and 13 of these have joined the Midland Medical Union.

The members of the clubs are divided in opinion. Many of the older members have become attached to their medical attendants and consider the increase of subscription demanded to be quite reasonable under the present and altered conditions of medical practice. It is among the younger and less experienced members that most of the disaffection is manifested and there are also certain committee men and leaders who in organising resistance seek to increase their personal influence and popularity These men have conceived a vast and far reaching scheme Not content with attending to the affairs of their own town they are striving to bring about joint action in one or two counties and to form under their directorship medical institutions which shall secure the exclusive services of several medical practitioners to be imported from outside so as to render the members of the clubs absolutely independent of the local practitioners. Fortunately the medical men at Chesterfield, in any case, are not absolutely dependent on club practice. It constitutes an important item in their incomes but if they lost all the clubs they would still be able to exist, though in somewhat reduced circumstances. Seeing that the medical practitioners are now organised and in union the medical union is able to hold its own against the clubs and to negotiate with them at least on a footing of equality Many meetings have been held between the medical practitioners and the representatives of the clubs and the points at issue have been discussed in a friendly manner But recently the Chesterfield practitioners were asked to meet delegates from outside and comparatively distant localities. Naturally they replied that they had no personal concern with those districts and that delegates of the clubs in these outlying districts should negotiate with their own local practitioners But the members of the clubs wanted to enlarge these conferences and by that means to increase the number of delegates on their committee, thus paving the way for a wide-spread amalgamation The Chesterfield practitioners thought it their duty to resist this tendency and the clubs retorted by a threat that a notice to quit would be served on all their medical officers in a week's time if they persisted in refusing to meet the larger delegation. Nevertheless this notice has not been given and indeed, by the terms of the agreements a three months notice must be given. As, however the quarter-day is approaching it is thought that perhaps a three months notice will be served. Indeed, negotiations are at a standstill, for the language recently employed by the representatives of the clubs was of so offensive a character that the members of the Chesterfield branch of the Midland Medical Union met and decided that they would not enter into any further conferences.

The two principal friendly societies at Chesterfield are the Druids and the Oddfellows The chief difficulty with the Oddfellows is that they wish to introduce women and children into their lodges. This is the old difficulty which exists in many towns and has been explained on several previous occasion The medical officer is willing to attend at club rates the bread winner who is a member of the Oddfellows. because when he is ill he has to forsake his business But when the Oddfellow is well and at work he can afford to pay for the medical attendance needed by his wife and family As it is, there is abuse enough without extending this to the women and children. For instance one of the Oddfellows at Chesterfield owns several shops and there are many tradesmen and others who could well afford to pay medical fees but who nevertheless come upon their club medical officer and expect to receive advice and medicine in exchange for the paltry 4*s* per annum which they pay These individuals are often ashamed to draw sick allowance from their club because this is entered in the books and receives a certain publicity But they can go to the club medical officer without anyone knowing anything about it Yet in all fairness it must also be said that a few Oddfellows when calling on their medical officer informed him that they did not come as club patient but that he was to charge them individually and at the usual rates

It is in respect to the Druids that the main difficulty has arisen. It appears that in the neighbouring town of Sheffield the Druids pay only 2*s* 6*d* per member per annum for medical attendance, and consequently many of them object to pay 4*s* at Chesterfield and argue that the medical men are very well off and make a very good thing out of the clubs If therefore, the men were to organise on a large scale they would be able to secure medical attendance at a much cheaper rate Accordingly some among them have determined to start a medical institute at Chesterfield, and though there is much division in their ranks they have attempted to advertise for a medical officer The medical press has refused to insert these advertisements and it is very important that the profession at large should know that in responding to such demands they will be helping to reduce the minimum of 4*s* established at Chesterfield to the half-crown level prevalent at Sheffield Some 15 years ago a similar effort was made and a medical officer was engaged by some benefit societies at Chesterfield, but it proved a miserable failure Debts were incurred and the medical officer was never paid the sums due to him To day the scheme does not give promise of much success and the advertisements for a medical officer were sent out before a house had been secured for the business of the medical institute which it is proposed to establish Then many of the lodges are not at all satisfied that this is a wise project, so that while the members of the profession present a united front there is division in the ranks of their adversaries

On June 12th, 1901, the Nottingham branch of the Midland Medical Union met and adopted and confirmed the two following resolutions which had been already carried by the Chesterfield and the Mansfield branches —

> First: "That in the event of any medical man receiving notice from any club through asking for an increase in fee no other practitioner should take the same even if offered to him "
>
> Secondly: ' That no member of this union shall assist by consultation or otherwise any practitioner in the counties of Nottingham and Derby who is declared by the Midland Medical Union to be opposed to the objects of the union '

Further, it was explained that at meetings held at Chesterfield and Mansfield it was unanimously resolved that a fund should be created to aid financially any of the members who might need such help in consequence of their adhering loyally to these rules The levy for this fund was not rendered obligatory, but it was decided that if any member who had not subscribed to the fund applied for relief it should be left to the discretion of the president and the vice president as to whether such relief should be given. Also it was resolved that the members should be asked to guarantee a maximum sum of five guineas and that they should be called upon to pay such proportion of the five guineas as might be needed to indemnify victims Thereupon sums amounting in all to 300 guineas were promised. From this it will be seen that there are all the elements necessary for making a good fight. Should any practitioner accept the offers made by the clubs and lend his services to the formation of a medical institute his position will not be an enviable one. If he should need a second opinion he will not readily find a consultant willing to help him He will be ostracised by all the members of the profession and will have for absolute master committees composed for the most part of working men whose language, manners, and mode of procedure are not always what a gentleman belonging to a liberal profession has a right to expect It is to be hoped that no member of the profession will lend himself to this endeavour to keep down the remuneration for professional work to a few halfpence per consultation. There are numerous medical charities available for the poor and all those who do not belong to the residuum of the extreme poor can well afford a penny per week, or the 4*s* a year minimum, demanded by the Chesterfield medical practitioners

SALE AND PURCHASE OF A MEDICAL PRACTICE

(FROM A LEGAL CORRESPONDENT)

AT some stage of his career nearly every medical practitioner has to consider the sale or purchase of a practice Whether he be vendor or purchaser it is useful that he should know something of the duties and responsibilities which are involved in such a transaction, and if he be vendor he should realise the legal nature and effect of the restrictions which he places himself under

The sale of a medical practice involves an agreement in restraint of trade which, unless limited, is contrary to public policy and which is *primâ facie* illegal If a man deliberately sells the right which all men have to the exercise of their calling he deprives the public of the benefit of his skill and experience, while he abandons what may be his means of livelihood A principle of law has therefore been evolved and clearly enunciated in the famous case of Mitchell *v* Reynolds (decided in 1712), to the effect that contracts in restraint of trade are void and must not be enforced by the courts In accordance with this principle if a medical man at the present day were to enter into a bond which prevented him from practising anywhere for the rest of his natural life no court of justice would enforce its performance While, therefore, contracts in total restraint of trade are void, it has become a well settled rule that if the restriction is limited as to area and if there is "consideration" for the bargain the goodwill of a medical practice, or, indeed, of any other business, may be made the subject matter of a valid contract of sale Hence the well known restrictive covenant into which the vendor of a practice enters is recognised in, and will always be enforced by, a court of justice Were it otherwise the sale of a connexion would be rendered impossible, as nothing could operate to prevent an out-going practitioner from interfering with the practice for which he himself has already received a substantial sum of money

It has been pointed out that the restriction must be limited as to space It would be wholly unreasonable, for instance, to prevent the vendor of a practice from exercising his calling anywhere in the British Isles Thus a general practitioner in London could not interfere with a Liverpool connexion, nor could a practice in Scotland be in any way prejudicial to an Irish practice Many cases have arisen in the courts as to what is a reasonable limit In Horner *v* Graves[1] it was held to be unreasonable to restrict a dentist from practising anywhere within 200 miles from York. On the other hand, to borrow an instance from the legal profession, a covenant preventing a solicitor from practising as such anywhere in England for 20 years was held to be reasonable and capable of enforcement (Whittaker *v* Howe[2]) It follows, therefore, that in marking the border line the court will be influenced in a large measure by the nature of the business The available means of communication are also important. By means of railways, telephones, &c., a practice can be extended over a much wider area at the present day than could have been possible at the close of the eighteenth century, so that a restriction which would have been held unreasonable in those days might now be considered capable of enforcement With regard to time there does not appear to be any restriction Nevertheless, if a man binds himself not to practice for a limited period the area of restriction may receive a slight extension The rule by which the boundary should be determined was thus expressed in the case of Horner *v* Graves (*ubi supra*) "The restraint must be such only as to afford a fair protection to the interests of the party in favour of whom it is given and not so large as to interfere with the interests of the public "

The consideration, an essential feature of every agreement for the sale of a practice, next requires attention So long as the court is satisfied that there is a consideration which is not merely colourable the contract will be enforced The adequacy of the consideration is left entirely to the parties themselves It would obviously be impossible for any tribunal to decide what is a reasonable price to pay for a medical practice Many instances could be cited to show what has been held to be a reasonable consideration In the case of Sainter *v* Fergusson[3] the engagement of the defendant as assistant was held to be sufficient consideration for an undertaking on his part not to practise within a radius of seven miles after the termination of his employment

Having made an attempt to indicate the features which are essential to every contract for the sale of a medical practice we now propose to consider what constitutes a breach of such a contract In most deeds the covenant is in the following form "The vendor undertakes that he will not [within certain limits] at any time hereafter directly or indirectly, and either alone or in partnership with, or as assistant to, any other person or persons, carry on the profession or business of a surgeon " A further clause prohibiting practice "in open competition" sometimes finds its way into the deed The question naturally arises What constitutes practising? Most medical men will be able to answer this question without any difficulty but doubtful points arise from time to time In the case of Palmer v Mallet[4] it was decided that a person acting only as a salaried assistant was carrying on the profession of a surgeon and that in doing so he was committing a breach of covenant The words open competition" were discussed in the case of Rogers v Drury[5] There the vendor agreed not to practise within a certain radius or directly or indirectly to compete with the purchaser He visited certain patients within the prohibited area at their own request. These patients moreover, had refused to call in the purchaser on any account. This was held to constitute an infringement of the covenant which the court said was not confined to active competition According to the legal maxim *Qui facit per alium facit per se* practice by an assistant is equivalent to practice by his principal. In the absence of any express authority upon the point it is probable that the vendor of a practice could be restrained by injunction from permitting his assistant to see patients in the proscribed district The establishment of a place of business such as a surgery is also unlawful. In the case of Newington v Bloxham (Feb. 6th 1897) the defendant, who had been an assistant of the plaintiff agreed not to practise within a five-mile radius after the termination, whether by notice or otherwise of his period of service He established a surgery within the five-mile radius The late Lord Chief Justice granted an injunction to restrain him from keeping the surgery open We have seen that to visit *quondam* patients even at their solicitation is a breach of contract. It would be otherwise if the patients were to travel to see the vendor in his new district, or probably if they saw him in consultation with and by the consent of the incoming practitioner Where partners in a firm have private" patients it seems that a member of the firm may be entitled to attend such patients after his retirement. So in the recent case of Harris v Mansbridge[6] the plaintiff practised as a dentist in partnership with the defendants. By the articles of partnership in the event of the death or retirement of any of the partners the partnership should continue between the surviving or remaining partners. By a subsequent agreement the plaintiff agreed to retire from the firm, the defendants taking over the management and control of the practice and the plaintiff agreed that he should not, during the term, see any of the patients of the defendants without their consent It was decided that this did not preclude the plaintiff from attending on those persons who had been his own patients exclusively while he had been a partner

---

[2] 3 Beav 383

[3] 7 C B 716

It must not be supposed however that every interference with a purchaser's practice constitutes a breach of covenant. The following case will serve to show how the court is likely to interpret the covenant where the vendor has interfered at the request of the purchaser In Rawlinson v Clarke[7] the defendant assigned to the plaintiff his practice as a surgeon and apothecary covenanting that he should not, nor would directly or indirectly by himself or in copartnership with any other person carry on or exercise his practice or profession of a surgeon or apothecary or either of them either by residing or visiting any patient, within the distance of three miles from the then place of business of the defendant. In case of any breach he undertook to pay £500 as and for liquidated damages and not as a penalty After the execution of this deed he attended several ladies in their confinements within the three months, and from one of them he received a fee of £14 14s It was proved however that he attended these persons with the plaintiff's knowledge and consent, and in consequence of a request by the plaintiff that he should continue to visit the patients in order to keep the connexion together It was held that this did not constitute a breach of covenant. It should perhaps be mentioned that even where a contract of service as an assistant may be put an end to by either party upon giving a month s notice the covenant not to practise within the prohibited radius may still be enforced (Giles v Hart[8])

An important question sometimes arises as to whether the contract is *personal* that is to say whether the rights and liabilities connected with it pass to an assignee In Jacoby v. Whitmore[9] a shopman had covenanted not to compete with his employer for a certain period The employer sold the goodwill to a third person who retained the shopman in his service. It was held that the right to enforce the obligation passed with the goodwill. From this we may infer that if a qualified assistant enters into a contract not to practise the subsequent sale of his master's practice does not release him from his obligation In the event, therefore of his committing a breach of covenant an action would lie against him at the instance of the purchaser of his former master s practice Where two men in partnership sell their goodwill on pain of a penalty for infringement of the covenant not to practise a breach by one partner involves payment of the whole penalty[10]

Although the main object of this article is to discuss the legal as apart from the medico-ethical aspect of contracts for the sale of a practice a few instances of what has been ethically considered a breach of contract may be appended. Thus the acceptance of an invitation to lecture upon a topic of medical interest within the proscribed area is not a breach of contract either legally or morally And in the absence of any agreement or bond of any kind it is considered a breach of etiquette for a *quondam* assistant to hold himself out for practice in the district frequented by his former principal although, of course, there is no legal remedy available against him Further although there is no implied legal undertaking on the part of a locum tenent not to practise in the immediate neighbourhood after his employment comes to an end, his doing so immediately is not considered honourable—but it is otherwise if he waits for a period of two or three years.

Having considered the various acts and defaults which are likely to constitute a breach of the contract the consequences of such a breach remain to be considered For this purpose it is necessary to refer to the form of penalty clause which is inserted in the deed. It usually runs That in case of any breach of the foregoing covenant he will forthwith pay to the plaintiff £2000 not in the nature of a penalty but as ascertained liquidated damages " Before citing any cases where the whole penalty has been enforced it is necessary to allude to the policy of the law with regard to penalties In all cases an action for damages lies for breach of contract provided the contract is legal and in proper form Sometimes however for the purpose of ensuring the due performance of an agreement the parties fix the damages beforehand and quote the figure as a penalty in the body of the contract. Nevertheless, a court of justice will occasionally go behind the express covenant and say Nay it is clear that the plaintiff has not suffered damage to this extent the enforcement of this penalty would be unjust as the exact injury suffered is capable of easy estimation." This rule is applied although the parties have agreed to regard the sum as liquidated—i.e. as ascertained damages. But where the proper measure of damages is difficult, if not impossible, to ascertain the court will, as a rule, enforce the covenant according to its very letter The latter expedient is usually adopted in the case of a contract for the sale of a medical practice. According to what scale it is asked could the value of a thing so shadowy be estimated? Bearing this in mind the vendor must be prepared to pay the entire sum agreed upon if he is found to be at fault unless indeed he is willing to consent to an injunction granted by the court at the instance of the purchaser with whom he has interfered for it was decided in the case of Carnes v Nesbitt[11] that the recovery and payment of a liquidated amount prevents an injunction being obtained the liquidated sum being regarded as the value of the practice for the stated period.

We have only alluded to the form of an ordinary bond for the purpose of showing the general nature of the restrictive clause. Other terms are sometimes added. Thus in the case of Reynolds v Bridge,[12] in addition to the ordinary covenant it was provided that notwithstanding the clause lastly hereinbefore contained, the defendant may after the determination of the term act in consultation with other medical gentlemen in W or elsewhere the defendant may also if he think fit, after the determination of the term attend midwifery cases in W and within 20 miles thereof but he shall pay one half of the fees which he shall receive for each of such midwifery cases unto the plaintiff so long as he shall continue to practice in W " It was decided in this case that the non payment of the midwifery fees would not be within the covenant, and failure to pay them would not have involved the defendant in liability to pay the penalty

[12] 6 E & Bl [illegible]

It is fortunate for the medical profession that disputes with regard to the interpretation of these covenants are few and far between. Indeed, the cases above referred to well nigh exhaust the list which can be made out after a search through the law reports In conclusion, it may be well to remind the intending purchaser of a goodwill that any breach, however slight, on the part of the vendor gives him the right to claim the penalty, while a false representation as to the value of the practice, if its falsity can be clearly proved, entitles him to demand rescission of the contract

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Manchester Royal Infirmary

A SPECIAL meeting of the Manchester Infirmary Board was held on Sept. 22nd, Sir F Forbes Adam being in the chair, when "22 out of 24 present members of the board expressed their intention to place their resignation in the hands of the trustees as soon as arrangements could be made for the proper appointment of their successors" It was thought that this course "would obviate the danger of misunderstanding and delay in the resettlement of the rebuilding problem." The present board will, however, remain in office and will continue to manage the affairs of the Royal Infirmary, the Royal Lunatic Asylum, and the Barnes Convalescent Home until the new board has been elected. According to the present rules this election can only take place at the annual meeting in February, so that a special meeting of the trustees will have to be called to pass a new rule authorising the election of a new board This action of the members of the present board seems to be in accordance with the general feeling It would be a misfortune, however, if none of them were chosen (and consented) to act on the new board Individually they are deservedly respected and would no doubt act loyally towards the scheme for rebuilding elsewhere, while the loss of their experience in the somewhat complicated details involved in the management of the three large institutions under their care would be most unfortunate. It is to be hoped, therefore, that while new blood is plentifully introduced there will not be the total loss of the old. The disposal of the present infirmary site is a matter of some difficulty The sum of £400,000 which the present board invited the corporation to give for it is prohibitive if it is regarded either as an open space or as partially occupied by a new reference library and art gallery, but it is said that two proposals are to be submitted to the new board one or other of which it is hoped may provide a way out of the deadlock with which we have been so long familiar

Public Washhouses

One of the conditions unfavourable to cleanliness and therefore to health among the poor of our large towns is that the appliances for the family wash are usually very imperfect and inconvenient, or perhaps in the poorest tenements scarcely existent After struggling with difficulties more or less unsuccessfully many a poor woman gives way in the end and resigns herself to a state of domestic dirtiness that would have shocked her when she first exchanged the country for the town. But after a time she becomes "acclimatised" and accustomed to dirt and so loses her wish for a better and brighter home Still even among these torn down and perhaps somewhat helpless women the provision of a public washhouse in their midst revives old feelings, and they soon become glad to make use of it In May last a public washhouse provided by the corporation was opened in Ancoats and up to the present has been used by 1650 women of the district. It was built at a cost of £700, but has probably been already paid for in the improved health and domestic comfort of the people There is accommodation for 20 workers at once and the average number for the week is 110 The charge made to each person is 1½*d* per hour It would be well for the community if inexpensive baths and washhouses were provided for the whole of the poor districts of Manchester Moss Side, adjoining, but municipally independent of, Manchester, is considering the question of building a swimming-bath and laundry for the district. The suggestion is to place the building on land immediately adjoining the refuse destructor, from which would be obtained the heat requisite for the baths and washhouse It is to be hoped that the scheme will be carried out, but with common sense and economy instead of the extravagance that has so often been a temptation to the spenders of public money to provide unnecessarily costly buildings, "which will be a credit and ornament to the city and worthy of Manchester" The poor and not the well to do should be more considered as their need is the greater

Epileptic Children and the School Boards

At the meeting of the Manchester School Board held on Sept 22nd it was decided that the board should take steps to carry out a scheme for providing a boarding school for epileptic children. It was explained that in conjunction with the Salford School Board it was intended to carry out the provision of the Elementary Education (Defective and Epileptic Children) Act, 1899, in so far as it related to those children who were unfit by reason of severe epilepsy to attend the ordinary public elementary schools It is proposed to place this joint boarding school as near Sandlebridge as practicable, with accommodation for 60 children. It is said that there are 40 cases in Manchester and, in proportion to the population, a greater number in Salford, but this probably is an under estimate. The land, buildings, furniture, &c., are expected to cost £14,400, while the annual charges for maintenance for the first 30 years, during which period the capital would be paid off, is estimated at £2354, and after that they would be £1618 This venture is undertaken in the hope that if these cases are dealt with in early life the disease may be arrested and cured, as indicated by "medical testimony and experience gained in Germany at Bielefield" But should this hope be disappointed and the school treatment prove ineffective, "the proximity of the site of the projected building to Sandlebridge, where the David Lewis Trust were erecting an epileptic home on a large scale, would enable the board by arrangement with the trustees to transfer the children to their care when they reached the age of 16" The guardians of the Manchester and Chorlton unions are about to provide both for young and adult epileptics, but it is doubtful if they would meet the case of the children under the care of the school board and the latter would not be pauperised by the scheme of the board As to the board being moribund, the proposer of the resolution said that it was not yet certain that it was moribund, but if the city council became the educational authority it would be grateful for not having to deal with the question *de novo*

A Strange Idea

An inquest was held at Heaton Moor a week ago on the body of a man who had drowned himself in the Mersey which illustrated an idea not uncommon among the half-educated classes The widow said that her husband thought that the police were after him for theft, but she did not think that he was going out of his mind, nor did she consult a medical man This was unfortunate enough, but the conduct of the next witness deserves special notice. He said that he saw the man in the Mersey and he seemed to be standing with his head and shoulders in the water When asked by the coroner he said that he did not try to get him out. "I did not know whether we could touch him before letting the police know, but I thought, 'Well, if he was struggling we might help him out, but this man was still.'" From what was stated it was clear that the deceased could not have been in the water many minutes and might possibly have been brought round if there had been proper help It is pretty certain that now and then a life is lost from the prevalence of this idea that a body must not be touched without the sanction of the police Both witnesses were disallowed their expenses, which may do as much towards educating the male witness as the admonitory remarks of the coroner who "was surprised there was such ignorance on the part of people."

Sept 23rd

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

South Dublin Union Hospital

A MEETING of the South Dublin rural district council was held on Sept 17th when a motion recommending the appointment of a committee to consider the advisability of changing the union hospital into a district hospital in which the patients would be permitted to wear their own clothes was passed. Mr Molloy, in opposing the motion, said that the existing hospitals in the city were more than sufficient to meet all the requirements of the people, except in the case of an epidemic, and inasmuch as they were most efficiently worked the board should be slow to cast any slur on their management It is notorious that Dublin is very largely supplied with general hospitals in comparison with London or with any other city in the United Kingdom As regards accommodation, the Mater Misericordiæ Hospital heads the list with its 330 beds filled at all times except during the vacation and cleaning season. There are eight other large clinical hospitals available for the citizens. They are all clinical hospitals of high class, efficiently managed and well known to all the medical profession in Ireland and to the public as well In reference to epidemic disease in Dublin the committee will find from the Registrar General s recent report that deaths from measles which numbered 20 16, 11 and 11 respectively during the four weeks ending on Sept. 6th fell to six in the week which ended on Sept. 13th. There is no epidemic disease in Dublin at present The committee will doubtless come to the conclusion that it is not advisable that the union hospitals should try to supplement the general hospitals in providing accommodation for the artisans of Dublin. A glance at the report of the Dublin Hospitals Commission will make it clear that the city is more than adequately supplied with hospitals suitable for the artisan

The British Association for the Advancement of Science

The meeting in Belfast of the British Association for the Advancement of Science which began on Sept. 10th came to a conclusion on Sept. 17th. It cannot be said that the proceedings of this year s meeting were marked by any very striking features. No new discoveries were brought forward no remarkable address was delivered and no great traveller genuine or not (like de Rougemont) appeared At the last meeting in Belfast in 1874 the numbers attending were 1951 in 1902 they were only 1620 notwithstanding the greatly increased population of the city In 1874 Tyndall and Huxley gave addresses which provoked the greatest criticism and were epoch making in their suggestiveness while the opening remarks made by Sir John Hooker in the Botanical Section on Pitcher and Carnivorous Plants were at that time quite new and original In 1874 owing to the great exertions of one of the most distinguished citizens of Belfast, the late Professor Thomas Andrews, Vice President of Queen s College, as well as those of Professor Peter Redfern, the Right Hon. Thomas Sinclair and Sir William Ewart, Bart. (the honorary secretaries of the meeting) the citizens of Belfast took the deepest interest in the work of this great scientific meeting This year the executive committee somehow failed to arouse the necessary enthusiasm, due it may be, as pointed out by a Belfast Citizen," in a letter to the local press, to the lack of business management on the part of the local organisers and paid officials." It would seem that the members of the ordinary committee (338 gentlemen) were never summoned to meet everything was left to the executive, finance, and hospitality committees, and on none of these was there a lady s name. As a result, many of the members of the general committee have, owing to the way in which they were slighted left the meeting severely alone and have neither joined the Association as pointed out by the Belfast Citizen " nor assisted in any way whatever As a result, unfortunately the people of Belfast did not take the interest they otherwise would have done (as was shown in the 1874 meeting) when they were appealed to by their own well known citizens One of the best sections was that of Education and as might be expected in Ireland, a discussion on any department of education in that country is lively Dr Starkie, the resident commissioner on national education (and one of the commissioners on university education) presented an indictment of Irish primary education but, owing to the remarkable papers and addresses of Dr W A. McKeown and others he found himself and his own department so freely discussed and condemned that he was in the position of defender and not of attacker From a medical point of view the paper by Dr W Graham (resident medical superintendent of the Belfast Asylum) on the Mental and Moral Characteristics of the People of Ulster attracted a good deal of interest and the smoking concert given by the members of the Ulster Medical Society on Sept. 15th at which about 250 gentlemen were present, was a great success. Professor W D Halliburton, the President of the Physiology Section gave an able introductory address on the Present Position of Chemical Physiology, and in the same section there were animated discussions on a paper by Professor Schäfer on the Diuretic Action of Pituitary Extracts, and on a paper by Dr J Turner on Some New Features in the Intimate Structure of the Human Cerebral Cortex.

Sept. 23rd.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Professor Virchow's Successor

NOTHING has yet been decided as to the successor of Professor Virchow in the chair of pathology at Berlin University and in the directorship of the Pathological Institute. It will be some time before any steps are taken in the matter because this is the season of the University vacation and it will not be until the end of October that the faculty of medicine will meet for the purpose of selecting candidates to be recommended to the Government. Professor Virchow's successor will therefore, not enter on his duties until the beginning of the summer semester and meanwhile the lectures will be delivered by Professor Virchow s assistants as during the time of his last illness. Some of the non medical journals state that owing to the great development of pathology since the time of Professor Virchow's entrance on his professorship the Government intends to divide the duties and to appoint two successors, one for the chair of pathological anatomy and the other for the chair of general pathology Undoubtedly this change would be in every way desirable. The daily papers, though of course, no authentic information is available, already give the names of probable successors, suggesting that Professor Orth of Göttingen, Professor Marchand of Marburg and Professor Ziegler of Freiburg will be candidates for the chair of pathology and that Professor Oscar Israel Professor Virchow's first assistant, will be a candidate for the chair of pathological anatomy There is also another vacancy in the Berlin Medical Faculty—namely the chair of clinical medicine held by Professor Gerhardt who died a few months ago.

Malaria on the Lower Elbe

Two years ago in his report on malaria Professor Koch pointed out that at that time disease hardly existed in Germany sporadic cases only being met with. Dr Mühlens, of the Institute for Tropical Diseases at Hamburg writing to the *Deutsche Medicinische Wochenschrift* now states that there is a form of malaria in the district of Ritzebüttel, near Cuxhaven Malaria in the epidemic form disappeared from this locality about 30 years ago and from 1898 to the end of 1900 no case occurred but in 1901 the disease reappeared and from February to July 1902, the two local medical men had no less than 130 cases to attend. The actual number of sufferers was, however considerably more than this, as most of them took quinine without seeking medical advice, and there was also a superstitious belief among the people that the disease, which they know as spring fever ought not to be treated in any way The medical men are of opinion that 30 per cent. of the population suffer from malaria or its effects and that no village or farm is free. Hitherto the disease has been of a mild character no death having occurred Anopheles maculipennis was stated to be present everywhere in the rooms of the dwelling houses as well as in the buildings occupied by domestic animals The houses are very unhygienic, the beds being placed as a rule in recesses from which fresh air is carefully excluded by curtains and in which the anopheles was found in great abundance. The cause of the sudden increase of the disease could not be ascertained.

Sept. 22nd.

EGYPT

(FROM OUR OWN CORRESPONDENT)

Prisons Department

THE annual report by Coles Pasha of the Egyptian prisons shows a series of well thought-out successful reforms due chiefly to the fact that money has been forthcoming from the Government for changes which have been badly wanted for the last 20 years of British rule There are now three convict, 13 central, and 80 local prisons accommodating altogether over 10 000 prisoners 16 men were executed during the year 1901 and 103 managed to escape, though nearly all of them were recaptured The general mortality shows a total of 17 per 1000, instead of 23 in the previous year Typhus fever broke out in the Alexandria prison and was traced back to some few cases in a small village prison, where there had been both overcrowding and underfeeding The mortality at Ghizeh, a large prison standing between Cairo and the Pyramids, is as high as 39 per 1000, and 17 out of the 29 deaths were accounted for by tubercle It is to be hoped that Dr Hodson, the newly appointed medical officer to the Prisons Department, will be able to prevent this high mortality in the future The reformatory for boys received 26 young criminals from Cairo judges during the year but only one boy was sent from the other big towns, showing that the provincial native judges have not yet discovered the advantage of not sending juvenile offenders to prison with the men Anyone who now visits the new prisons in Egypt can hardly believe how bad they were a few years ago

Medical Practitioners in Egypt

The number of Greek medical men is always increasing, and, of course, the British have increased greatly in numbers since the beginning of the occupation A list recently compiled at the central office of the Sanitary Department shows that there are now 1211 medical men of all nationalities in Egypt 604 are Europeans, 85 hold a Persian or a Turkish diploma from Teheran or Constantinople, 45 are natives with a European diploma, and the remaining 477 are natives educated in Cairo at the one medical school of the country It will be noticed that the foreigners considerably outnumber the Egyptians, though there are 90 times more of the latter than the former residing in Egypt The last published statistics give 38 9 per 1000 as the native birth rate throughout the whole country and 21 8 as the death rate As might be expected, the lowest mortality is in the desert districts and the highest is in the largest towns

Cairo Sept 15th

CANADA

(FROM OUR OWN CORRESPONDENT)

The Small-pox Records of Toronto and Montreal Compared

SINCE Jan 1st there have been 500 cases of small pox in Montreal and only 28 in Toronto There have been no cases in Toronto for some time but Montreal has still four cases. The number of deaths in Montreal was 11, in Toronto one In Montreal 432 of the patients had never been vaccinated

Health of Toronto for July

The vital statistics for July show 425 births, 222 marriages, and 245 deaths, compared with 352 births 241 marriages, and 303 deaths for the same month of last year The total births to date for 1902 are 2899, an increase of 318 over the figures of 1901 The increase in the number of births is in large measure due to the stricter regulations with regard to the registration of births adopted by the civic authorities

Laval University, Montreal

Two professors of Laval University sailed on August 21st for Rome to attend the fourth international congress of the professors of gynæcology and obstretrics They are Dr L. N Delorme and Dr M. T Brennan of Montreal —Dr Telesphore Parizeau has been appointed professor of pathology and clinical surgery to succeed the late Dr J A. S Brunnelle Dr Parizeau is a graduate of Laval University and after receiving his degree he spent several years in the hospitals of Paris He is a member of the visiting staff of Nôtre Dame Hospital, Montreal

The Toronto Asylum for the Insane

The Government of Ontario has in contemplation the removal in the near future of the Toronto Asylum for the Insane On account of the increased value of the present property—which is in the very centre of the western portion of the city—owing to the progress westwards of large manufacturing concerns, it has been thought that it would be profitable to the public and to patients alike if the institution were removed to a point some miles beyond the city limits. The present site, although large, is not considered sufficient for the employment of 800 inmates, and the proposal is to secure a farm of 300 acres whereon to erect new buildings on the cottage plan In addition the provincial authorities have in contemplation the introduction of physical culture as an educational factor into all the asylums of the province This innovation will first be experimented with in the Asylum for Idiots at Orillia, Ontario

The Unborn Child Co-heir with other Children

Mr Justice Lount of Toronto has recently rendered a judgment both unique and interesting Some few years ago a resident of western Ontario died leaving a widow and four children Four months after his death a fifth child was born. The case arose over the division of a $2000 insurance policy which according to the will was to be equally shared among the widow and children The administrators applied to the courts for advice as to whether or not the infant child born after the death of the father was entitled to a share in the insurance money Mr Justice Lount ruled that a child, although unborn, is still a child in law, and takes rank as a child living at the death of its parent. The case is said to be the first of its kind ever tried in Canada.

Canadian Criminal Statistics

The Dominion Statistician has recently issued a bulletin on the criminal statistics of Canada for the year ending Sept. 30th, 1901. The number of charges for indictable offences was 128 less in 1901 than in 1900, being 8291 in the former year and 8419 in the latter The convictions were 5638, or 130 less than in 1900 As regards the abuse of alcohol and crime, in 1899 the immoderate drinkers numbered 33 5 per cent of the convicted criminals, in 1900 25 1 per cent., and in 1901 nearly 30 per cent About one-third of the criminals were persons addicted to drinking Crime has increased disproportionately amongst juveniles of the male sex. This is reckoned to be the most serious item in the records of crime in Canada for the year 1901.

Montreal General Hospital

The revenue for the second quarter of the year 1902 at the Montreal General Hospital amounted to $18 660 and the expenditure to $23,995 For the first six months of the current year the revenue was $7500 less than for the corresponding time last year During the quarter 716 patients were admitted into the various wards, while in the outdoor departments the number treated amounted to 8108

French Medical Society of North America

The first meeting of this newly-organised medical association of the French practitioners of the United States and Canada was held in Quebec city in the latter part of June. There were over 200 delegates present to listen to and to discuss 80 papers The next meeting is to be held at Montreal in 1905 under the direction of the following officers —President, Dr Foucher, Montreal , first vice president, Dr Ahern, Quebec , second vice president, Dr Petit, Nashua, Newhaven, U S A. , third vice-president, Dr Rouleau, Calgary, North West Territory, Canada , general secretary, Dr Le Sage Montreal , secretary for Quebec, Dr A. Simard , treasurer, Dr Boucher, Montreal

Toronto Sept 12th

(FROM OUR OWN CORRESPONDENT)

Suicide Record of 1901 in the United States

SELF DESTRUCTION is gradually increasing in the United States Mr Frederick Hoffman, a well known expert on the subject, gives in the *Spectator* tables of comparative statistics of suicide It is shown by one of these tables that the average mortality from suicide during 1891–1900 was equivalent to a rate of 15 7 per 100,000 of population During the year 1901 the rate was 16 6, an increase of 0 9 per 100,000 of population During the year 1901 the suicidal frequency was not exactly the same as established by the 10 year average, but generally speaking the cities subject to an excessive mortality from suicide maintained their respective ratios during successive years Of the 50 cities in the United States tabulated by Mr Hoffman, 31 show an increase in the rate, while 19 show a decrease when the year 1901 is compared with the average for the preceding decade. The city having the highest ratio during 1901 was Hoboken, N J , while the city having the lowest was Fall River, Mass. The 10 cities with the largest suicidal frequency are St. Louis, Mo , Chicago, Ill., Hoboken, N J , Oakland, Cal , New York city proper , Millwaukee, Wis Cincinnatti, Ohio , Newark, N J New Orleans La. and Brooklyn N Y If the aggregate returns of 50 cities are compared for individual years since 1890 it is shown that the increase in the suicide rate has been quite gradual and persistent. The rate for 1890 was 12 0 per 100 000 of population increasing to 15 6 by 1895 and to 16 6 by 1901 The rates however, were highest during the two years 1897–98. If the rate prevailing during the first six years be compared with the last six years it is shown that the average mortality from suicide was 14 4 per 100 000 during 1890–95, against 16 5 during 1896–1901. Thus, no other conclusion can be reached than that a further increase in the rate of suicidal tendency in the cities of the United States may be anticipated during the coming decade. It would be interesting for the sake of comparison to collect the statistics of suicide in Great Britain and the European continent.

Reorganisation of the Public Hospitals of New York City

The public hospitals of New York City during the past few years have been subjected to much adverse criticism by the medical and lay press, on account both of their construction and management These hospitals are four in number—Bellevue and three subsidiary ones Gouveneur Harlem and Fordham The chief scandals have emanated from Bellevue, an institution which usually accommodates about 950 in-patients and has perhaps the largest out-patient department in the world The strictures passed by the press on the establishments, together with a strong public feeling of indignation aroused by accounts of the ill treatment and neglect of patients eventually decided the authorities to appoint trustees to report to the mayor of New York the condition of affairs and to propose remedies for the same. The trustees are 10 citizens of good standing the president being a physician of wide experience in hospital matters. The first report has just been handed in and deals with the inadequate facilities for the reception and examination of patients the overcrowded sleeping rooms of the house staff, the dark and unwholesome quarters of the employées, the indecent conditions in the prison wards the unsatisfactory methods of cooking and serving the food to the patients, and the antiquated and insanitary character of the plumbing throughout the hospital This report refers especially to Bellevue. It says "Some of these conditions we have been able to improve , others in spite of all our efforts, remain practically unchanged. They can only be remedied in our opinion, by the erection of an entirely new Bellevue Hospital in the place of the collection of buildings that has borne the name for so many years." When it is said that the main structure, which contains 718 of the 939 beds in the whole hospital, was erected in 1817 and was used as an almshouse until 1846 the justice of the report will be clearly apprehended The report enters fully into the inconvenient and insanitary conditions which prevail at Bellevue and its allied hospitals and then gives an account of the improvements which the trustees have been able to effect. Two administrative changes of great importance which have been introduced in Bellevue are given in detail, one being the reorganisation of the nursing service and the other changes in the pavilion for the insane. The nursing service at Bellevue has been hitherto divided between two schools, the New York Training School for Women Nurses and the Mills Training School for Male Nurses. The former school has had charge of the wards for women and children and the latter school of the wards for men. The trustees have concluded that there should be a woman head nurse in charge of every ward in the hospital with the exception of the male prison ward, the male alcoholic ward and the male genito-urinary wards. Male nurses will be trained and graduated as before but in somewhat smaller classes. A committee on nursing consisting of two members of the medical board and two members of the board of managers of each of the training schools will supervise the general policy of the nursing service of the whole hospital. Many changes have been enforced in the pavilion for the insane, which however cannot be here particularised for lack of space The trustees especially dwell upon the crying need of a new Bellevue Hospital and urge upon the municipal authorities that as the construction of a hospital of such magnitude will necessarily extend over several years it should be authorised at once. In a later letter I will refer again to this matter as it is one of far more than local interest.

Sept. 17th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT)

Public Health of Victoria

THE bubonic plague seems to have died out, for the present at all events No fresh cases have been reported in any of the States during the past month. Influenza is again prevalent and deaths from pneumonia have increased. The Board of Public Health of Victoria has decided that the diseases known as pyæmia, septicæmia, puerperal fever metria, and pelvic abscess shall be deemed to be dangerous, infectious, or contagious diseases for the purposes of any Act relating to the public health

The Milk-supply of Melbourne

Dr Norris, assistant medical inspector of the Board, has recently submitted a report on the milk supply of Melbourne. He had inspected 1104 premises in 564 of which 4865 cows were milked. Of these cows 1023 were grazed on open unfenced land. In 155 premises no special precautions were used to ensure cleanliness. In 360 the cow yards and in 287 the cowsheds, were unsatisfactory from a sanitary point of view The provision for the storage of the milk was unsatisfactory in 50 per cent. of the registered dairy premises. The unsatisfactory conditions bore an inverse ratio to the degree of attention bestowed on the subject by the local sanitary authorities. Defects were less general in districts where inspections had previously been made by officers of the board

Lunacy Department in Victoria.

Mr McCreery inspector-general of lunatic asylums for Victoria, has presented his annual report He maintains, with force that the control of the asylums should be placed under one body with undivided authority instead of being as at present, distributed among the chief secretary the master in lunacy the Public Service Board the Tender Board, the Department of Public Works and the Crown Law Department. The present system means loss of time and of money and is detrimental to the patient's interests, while the powers of the inspector and of the official visitors to make inquiries are of little use, because no provision is made to give administrative effect to the results of their inquiries. He recommends that the Kew Asylum should be reserved for patients likely to recover and that the chronic cases should be sent to other asylums. He adds that if the much needed pay cottages were built the improved treatment of many cases would be made possible

Deaths in Melbourne Gaol of non Criminals.—Censure of Medical Men.

Quite recently two men quite innocent of any offence against the laws were taken to the Melbourne Gaol and there died The first case was that of a man who was taken to the Melbourne Hospital and was refused admission owing to want of room and who by a series of misunderstandings and blunderings, was handed over to the police and taken to the gaol, where he died. At the inquest the jury in a rider censured the hospital authorities. The hospital committee censured the resident medical officer concerned. In the second case a lunatic who had been running about the streets unclothed was brought before the magistrates and remanded to gaol on a charge of "insulting behaviour" The medical officer of the gaol, Mr O G Godfrey discharged him to the police as a proper subject for a lunatic asylum , he was brought before the court and again remanded to the gaol, where he died two days later The coroner in summing up at the inquest, said that the cause of death was very clearly proved to be broncho-pneumonia. He could not see that any material error had been made in connexion with deceased's treatment but it was for the jury to say whether they considered that the arrangements made for the treatment of persons who, innocent of crime, were yet liable to be sent to the gaol were satisfactory It was obviously the duty of the authorities to provide a fit place for the reception of persons supposed to be suffering from insanity The jury found that the man's death was accelerated by the action of the medical officer of the gaol and they found him guilty of manslaughter The verdict was unanimously regarded as ridiculous and the Crown entered a *nolle prosequi*

The Profession and the Press

When the cablegrams concerning the illness of the King and the operation upon His Majesty reached the various cities in Australia, almost all of the newspapers published opinions from leading surgeons concerning the nature of the case and its probable result. In Sydney alone has any disapproval been expressed of the action of the medical men who allowed their opinions to be published. At a meeting of the New South Wales branch of the British Medical Association held on July 25th, Dr R. Worrall moved the following addition to the articles of association —

> No member of the New South Wales Branch of the British Medical Association engaged in private practice shall allow himself to be interviewed on professional matters by representatives of the lay press without a written undertaking that his identity shall not be disclosed

The meeting was largely attended and the matter was freely discussed. Dr Fiaschi challenged Dr Worrall to show any precedent for such a resolution and he proposed as an amendment that medical men should not give interviews to the lay press on medical subjects unless they were of national or public importance. He spoke very vigorously in favour of absolute freedom of speech and contended that medical men should not sink their individuality A prolonged discussion followed, the general feeling being that the interviews in reference to the King's illness were given under such circumstances of public interest as to warrant the action of the medical men who gave them. Dr Fiaschi's amendment was negatived by one vote Dr Wilkinson then moved that, as there were evidently two sides to the question and opinions were nearly equally divided, "the whole question be allowed to lapse" The chairman, Dr Rennie, declared this motion lost, but Dr Wilkinson called for a division which resulted in a large majority for his motion. The matter has been much discussed in the Sydney press and the proposal to "gag the profession," as it is termed, condemned The newspapers claim that the public has a right to information in such cases, and as the press looks to acknowledged leaders of the profession for such information, it is also right that the public should know who gives the opinion and what weight it carries

Attempt to Amend the Medical Act of New South Wales

On July 15th the second reading of the Medical Practitioners (Amending) Bill was moved by a private member in the Legislative Assembly of New South Wales It was a bold attempt to legislate for an individual who wished to be registered but was precluded by the present Act as he had just fallen short of the three years' course prescribed Fortunately the attempt failed and the Bill was left in a curious position, the motion "that the Bill be read a second time" being left with the word "that" standing alone, and unless another amendment is moved it lapses

Hospital News

The annual meeting of the governors of the Melbourne Hospital was held on July 24th. The report of the committee stated that by economising and by adopting new means of raising revenue the deficit had been nearly wiped out. The number of patients who have received treatment during the year had been 21,474 and of these 4444 were admitted to the wards and 17,030 were treated in the out-patients' department There had been 726 deaths, 245 of which occurred within 72 hours after admission. Several improvements had been effected in the building and other improvements and alterations were proposed.—The annual meeting of St. Vincent's Hospital, Melbourne, was largely attended and the reports which were read were very satisfactory The total receipts amounted to £3321 and the expenditure to £3205 The first section of the new buildings is in course of erection and will accommodate 80 patients 496 major operations were performed with a death-rate of 3 per cent. and 10,440 patients were treated during the year—The report presented at the annual meeting of the Victorian Eye and Ear Hospital stated that the total number of in patients treated during the year was 805, and the out-patients (distinct cases), 5549, this being an increase of 131 over the previous year The number of attendances of out patients was 30,017, being an increase of 1226 The number of operations performed was 1124 The revenue derived from all sources was £3750, and the expenditure was £3501 The necessity for enlarging the accommodation for out patients, referred to in the previous report, still existed, and was, in fact, becoming more and more accentuated There was also urgent need for more accommodation for in patients as at present many patients who ought to be admitted to the wards had to be refused. The most urgent of these cases had to come every morning to the hospital to be treated during the day as in patients, returning to their homes or to lodgings for the night.—The Sydney Harbour Trust Commissioners gave notice to quit to the committee of the recently established King Edward Hospital, and as the committee did not remove an ejectment was executed on July 10th The patients were conveyed to the Sydney Hospital and the Coast Hospital in ambulances under the supervision of the medical officer of the Board of Health, the medical superintendent of the Sydney Hospital, and the medical officer of the Coast Hospital, who were satisfied that the patients were fit to be removed The Harbour Trust Commissioners then took formal possession of the building

Death of Mr T Westbrook.

The death is announced of Mr Talbot Westbrook, M.R.C S Eng, L.A.H Dub He studied medicine at Guy's Hospital and completed his course in 1871 He practised in England until 1890, when he came to Nunnukah, in Victoria, and subsequently removed to Narrendua, in New South Wales His health failed and he relinquished practice some two years ago

August 18th

Obituary.

ADOLFO TARGIONI-TOZZETTI

Full of years and honours the emeritus professor of "comparative anatomy and the zoology of the invertebrates" in the Florentine medical school has gone over "to the majority" He died at Careggi, at the Villa Corradi, on Sept. 18th, and was followed to the grave by a funeral *cortège* which included representatives of nearly every association in Italy devoted to medicine and nature study Not the least distinguished of a family in which scientific and literary predilection seems hereditary, Adolfo Targioni-Tozzetti was born on Feb 13th, 1823, in Florence, and after the usual preliminary instruction enrolled himself as a student in the medical faculty of the local seat of learning In 1848 he graduated with the highest honours and on the same day, being then 25 years of age, he was appointed assistant professor of botany and materia medica in the Scuole di Farmacia e di Materia Medica attached to the great hospital of the Santa Maria Nuova. Even before graduation his ardour and distinction in nature study were recognised far beyond the precincts of the Florentine school, securing him, among other honours, that of corresponding fellow of the Accademia Medico Fisica of Milan. He was an admirable lecturer, gifted with a power of lucid exposition and vivid expression that led to his appointment to various commissions under Government, such, for example, as that instituted by the Ministry of Commerce and Agriculture to inquire into the fishing industry and its conditions in Sweden and Norway These engagements proved a welcome interlude to his indefatigable work in the laboratory, particularly with the microscope, alternating, on occasion, with zealous intervention in patriotic duty, as in the cholera epidemic of 1854, when he acted as "medico straordinario" and in the war of independence in 1859 when, as regimental surgeon, he worked not less energetically and usefully

In 1855 by "sovereign rescript," he succeeded his illustrious kinsman, Antonio Targioni Tozzetti, in the chair of botany and materia medica—the post in which he had been assistant, thereafter he was appointed professor of natural history as applied to the industrial arts, and, further, was promoted to the chairs of pharmaceutical botany and materia medica in the Royal Istituto Tecnico and of Clinica Agraria in the Agrarian Institute at the Cascine. By this time honours from European universities, academies, and learned societies flowed in upon him apace, till the list numbered between 20 and 30 "corresponding fellowships" In 1860 he was nominated in the Reale Istituto di Studi Superiori to the post which he held with brilliant acceptance till 1900, when severe illness laid him aside—the professorship of comparative anatomy and the zoology of the invertebrates, a department in which he turned out year by year accomplished and enthusiastic scholars many of whom are now professors of the same subject in the various medical schools of Italy Always practical in his activity he took the deepest interest in mology in its agricultural bearings and laid the wine l olive culture of Tuscany in particular under lasting gations. To him indeed the Stazione di Entomologia aria di Firenze owes its origin and from 1875 till year when illness suspended all his work he took leading part in its investigations and reports In B, on completing his seventieth year the occurrence commemorated by a *festa* in which his colleagues, pupils, and his fellow-citizens, without distinction creed or party put on record their appreciation of his work and their admiration and love of him as a man. m London from Stockholm and St. Petersburg from ris, from Berlin, and from Vienna, to mention the leading itals, he received congratulatory messages from the atest *savants* of the day attesting the value of his dis- eries, of his improvements on accepted doctrine, and of his tributions generally to the cause of nature-study On that asion the old man eloquent" made worthy acknowledg nt of the distinction conferred upon him and returned to e laboratory and to the professorial chair with an energy d enthusiasm surprising in one of his years But as the ntury drew to a close signs of senile degeneration gradually clared themselves, resulting in the acute illness to which, ter struggling nobly against it for many months, he finally ccumbed in the well-earned repose of the Villa Corradi.

ARTHUR BARRY BLACKER, M.D, B.S. DURH L.R.C.P LOND, M.R.C.S ENG

WE regret to have to announce the death of Dr thur Barry Blacker which occurred on Sept. 17th thur Blacker was the son of the late Rev Maxwell acker who was well known as a scholar and an admirable anslator of mediæval Latin hymns. His son was educated the Merchant Taylors School where he remained until he tered at St. Thomas s Hospital as a medical student In 83 he became a Licentiate of the Society of Apothecaries London and a Member of the same corporation in 1891. e received the Member s diploma of the Royal College of rgeons of England in 1884 and graduated at the University Durham as M.B in 1885 proceeding to the degree of M.D 1890 In November 1889 he went to Egypt and acted resident physician at Mena House Cairo, for two nters He held various appointments at St. Thomas s Hospital and for some time acted as assistant electrician to St. Bartholomew s Hospital Soon after the introduction of he x rays he was made superintendent of the x ray department at St Thomas s Hospital and also at the hospital for nsumption at Brompton and in this department of ientific knowledge he did a great deal of useful work. For some six months before his death he was unable to do ctive work although he saw patients up to the month of June.

Arthur Barry Blacker was an earnest and devoted Churchman. He took much interest and did a great deal of unostentatious and valuable work in the parish of St. Barnabas, Pimlico. He was one of the church wardens and for some time physician to the Dispensary of St. Paul and St. Barnabas, a charitable institution which was supported by the parishioners. He was buried on Sept. 20th at Putney Vale Cemetery In the early morning there was a private celebration of the Eucharist, attended by the members of the family and the first part of the burial office was sung in the church at 11.30 The building was quite full and many went on to the cemetery Among the wreaths were those sent by the staff of St. Thomas's Hospital and a special one from the x ray department, by the Roentgen Society by the Clinical Society and by the St. Barnabas Orphanage. The coffin was covered with the beautiful pall belonging to the church The vicar and the Rev C. O Becker for some 17 years assistant curate of St. Barnabas, together with the choir accompanied the body to the cemetery and there were laid to rest the mortal remains of one of whom it may well be said—

And full of kind deeds simply done
Were all his days"

THE PREVALENCE OF SMALL POX.—Only two ases of small pox have been admitted to the hospitals of the Metropolitan Asylums Board since Saturday Sept 20th—namely 1 on Sept. 22nd and 1 on Sept 24th.

THE ELECTION OF A DIRECT REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL

As we go to press we are informed that the result of the election for a Direct Representative on the General Medical Council is as follows —

SIR VICTOR HORSLEY	7672
MR. JOSEPH SMITH	3105

Medical News

UNIVERSITY OF DURHAM —At the examinations for the degree of Bachelor in Medicine held in September the following candidates satisfied the examiners —

FIRST EXAMINATION

Elementary Anatomy and Biology Chemistry and Physics —Second-class Honours: Frederick Charles Pybus, College of Medicine, Newcastle-upon Tyne. Pass List: Horsley Drummond and Walter Nicholas Johns, College of Medicine, Newcastle-upon Tyne; Hector Graham Gordon Mackenzie, M.A. Edinburgh Medical School and George Robert Philipson and David Ranken College of Medicine, Newcastle-upon Tyne.

Elementary Anatomy and Biology —Helen Young Campbell, London School of Medicine for Women; Lewis Augustus Clutterbuck, L.R.C.P & S Ed., L.R.C.P I., Catholic University Dublin and College of Medicine, Newcastle-upon-Tyne; Hamilton Drummond, College of Medicine, Newcastle-upon Tyne; Camilla Lucy Heek rath London School of Medicine for Women; Florence Barrie Lambert and Jessie Jean Martin Morton Edinburgh Medical School; Jessie Margaret Murray London School of Medicine for Women; Norman Spedding, College of Medicine, Newcastle-upon-Tyne; and Eric Frushard Waddington Yorkshire College Leeds.

Chemistry and Physics —Vincent Edgar Badcock, College of Medicine, Newcastle-upon Tyne; Thomas Henry Bishop, M.R C.S., L.R.C.P Edinburgh University; George Edward Peckett Davis, George Denholm Neville Avory Eddlestone John Charles Norman, Geoffrey Pybus Richard Woodward Swayne and Lionel Langford Westrope College of Medicine, Newcastle-upon-Tyne; Frank Whitby St Bartholomew s Hospital; and Thomas Leathard Wormald, College of Medicine Newcastle-upon-Tyne

SECOND EXAMINATION

Anatomy, Physiology and Materia Medica.—First-class Honours: James Glenny Gibb St. Bartholomew's Hospital. Second-class Honours: Lillie Johnson B.Sc. College of Medicine, Newcastle-upon Tyne; William Edward Hopkins University College, Liverpool; Arthur Alan Miller M R C.S., L.R.C.P Guy s Hospital; and Francis Henry Moxon, College of Medicine, Newcastle-upon-Tyne. Pass List: Arthur Edward Clayton L.R.C.P and S. Edinburgh School of Medicine James Henry Cooke, B Litt., William Cowden, Hugh Boyd Cunningham, William Ernest Falconar Arthur Beresford Jones Cyril Claude Lavington, William Ernest Craven Lunn Ernest Martin and Charles Duncan Relton, College of Medicine, Newcastle-upon Tyne; Oswin Shields, M.R.C.S. L.R.C.P St. Mary s Hospital; and Richard Geoffrey Shaw Simpson, Frank Tomlinson Simpson Edward Tate, and Tys Visser College of Medicine Newcastle-upon Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna* Dr P L Gardini has been recognised as *privat docent* of Midwifery and Gynæcology —*Budapest* Dr J Böke *privat-docent* of Otology has been promoted to an Extra ordinary Professorship —*Gratz* Dr Erwin Payr *privat docent* of Surgery has been promoted to an Extraordinary Professorship —*Innsbruck* Dr Oscar Zoth of Gratz has been appointed to the chair of Physiology vacated by Professor von Vintschgau who is retiring —*Kiel* Dr R. O Neumann has been recognised as *privat-docent* of Hygiene.—*Lausanne* Dr Casimir Strzyzowski has been appointed Extraordinary Professor of Clinical Medicine.—*Philadelphia (Jefferson College)* Dr Thomas G Ashton and Dr. Julius L. Sallinger have been appointed Professors of Clinical Medicine.—*Prague (German University)* Dr H Schloffer *privat-docent* of Surgery and Dr Kleinhaus and Dr Knapp, *privat docenten* of Midwifery and Gynæcology have all been promoted to Extraordinary Professorships.—*Strasburg* Dr A. Stolz has been recognised as *privat-docent* of Surgery —*Turin* Dr Gasparo D Urso of Rome has been appointed to the chair of Surgical Pathology —*Vienna* The rank of Ordinary Professor has been conferred on Dr S. von Basch Extraordinary Professor of Experimental Pathology on Dr L. Oser Extraordinary Professor of Medicine and on Dr Aloi Monti Extraordinary Professor of Pædiatry Dr A. Schattenfroh *privat-docent* of Hygiene, has been promoted to an Extraordinary Professorship —*Warsaw* Dr Gendre of St Petersburg has been appointed Extraordinary Professor of Physiology

South Devon and East Cornwall Hospital, Plymouth.—The new out-patient department of this hospital has just been opened The building, which was much required, has been erected at a cost of £2000

Hospital for Sick Children, Great Ormond-street—The Emperor of Germany has, through the German Ambassador, accepted from Mr Richard N Speaight for his private library a copy of "Children's Portraits" which he lately compiled with the object of raising £1000 towards the funds of the Hospital for Sick Children, Great Ormond street, W C The copy was specially bound in vellum and Russia leather similar to the one presented to the Queen Messrs F and R Speaight still have a few copies left, which may be obtained for half a guinea each on application at their studio, 178, Regent-street, London, W

The Lucas Bed at the London Temperance Hospital.—The members of the National British Women's Temperance Association have endowed a bed in the London Temperance Hospital, Hampstead road, to perpetuate the memory of Mrs Margaret Lucas sister of the late Mr John Bright. Mrs Lucas was the first president of the association, an ardent worker in the cause of temperance, and a munificent benefactor of the London Temperance Hospital The £1000 necessary for the endowment of the bed have been raised through the efforts of the members of the branches of the association, aided by Miss Orme, late the matron of the hospital, to whom the movement owes in a great measure its origin Some £600 have been previously handed over to the board of management and the final instalment was given to them on Sept. 23rd The proceedings took place in the board room of the hospital The members of the association, of which Lady Henry Somerset is president, were cordially welcomed by Mr Alderman T Vezey Strong, chairman of the hospital, who in a brief speech alluded to the warm interest evinced by Mrs Lucas in the institution Mrs Aukland, honorary vice president of the association having briefly narrated the origin of the scheme, Lady Henry Somerset handed to the chairman a cheque for £400 in completion of the endowment She referred to the unceasing labours of the sister of the distinguished statesman and expressed her conviction as to the great importance of the coöperation of women in the multifarious work associated with hospital management Mr Alderman Strong, in accepting the gift on behalf of the hospital, tendered the hearty thanks of the board to the members of the National British Women's Temperance Association for the spirit that had animated them, which, he hoped, might be emulated by others —The proceedings were brought to a close by the singing of the National Anthem

Presbyterian Mission Hospital, Miraj—The Presbyterian Mission Hospital at Miraj, in the southern Mahratta country, was established in 1892 in connexion with the Western India Mission of the Board of Foreign Missions of the Presbyterian Church in the United States of America. The report for 1901 states that the attendance of in patients was 92 less than that of 1900, which was attributable to the presence of plague in the town of Miraj for the greater part of the year Of the patients treated 507 were males, 212 were females, 500 were entered as surgical (which includes all eye cases), and 219 as medical. The average duration of treatment was 21 days. The average daily attendance was 51. The average distance travelled by each patient in coming to the hospital was 43 9 miles There were 55 deaths—namely, 25 among the surgical patients and 30 among the medical patients, the latter included seven deaths from plague and four from malignant types of fever 702 operations were performed, 33 of them being abdominal, of the remainder, the greatest numbers under separate headings were 170 cases of extraction of cataract, 56 of iridectomy for leukoma 31 of litholapaxy for vesical calculus, 27 of osteotomy for necrosis and caries, and 10 of division of anal fistula. There were also three cases of rhinoplasty for contracted nares, and in connexion with this it is mentioned that some years ago a man who had lost his nose as the result of 'an enemy's grudge" came to the hospital for the purpose of having a new one made He had been wearing a wooden nose made by a carpenter and painted the colour of the skin, it was not a bad imitation and was set over the nasal cavities in place of the absent nose, being held in position by a string tied round the head The wearing of a pair of blue spectacles completed the artistic

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institut and others possessing information suitable for this column, invited to forward it to The Lancet Office directed to the Editor not later than 9 o clock on the Thursday morning of week for publication in the next number

Alexander T D, M.B, B Ch, B A O Dubl has been appoi Certifying Surgeon under the Factory Act for the Porth District of Glamorgan

Askew J R, L R C P & S Edin L F P S Glasg, has been appoi Medical Officer of Health for the Fochabers Ward of the B Parish Aberdeen

Beaton **Wm Leslie** M B Ch B Aberd has been appointed Ju House Surgeon to the West Ham and East London Hospital E

Booth Clarkson James L R C P, L R C S Edin late Medical Of in charge of Troops for the District of Molteno Cape Colony, been appointed District Surgeon and Health Officer for the Dis of Umzinto Natal

Brown J M B Ch B Vict has been re-appointed Medical Offic Health for the Borough of Bacup

Casey E M D Lond has been re appointed Medical Officer of He to the Windsor Town Council

Crowther Smith S F M B Lond has been appointed Certif Surgeon under the Factory Act for the Liss District of Hants.

WILLIAMS.—On Sept. 10th at the Fleet Surgeon's House Royal Marine Barracks, Plymouth the wife of Dr J C B Williams of a son.

MARRIAGES

COWIN—BYERS.—On Sept. 22nd, 1902, at Christ Church, Sunderland, by the Rev C. G Hopkinson M A Captain Douglas H. F Cowin, I.M.S, to Ethel daughter of William Lumsdon Byers.

GULLAN—GOODWIN —On Sept 17th at St Saviour's Church Oxton, Birkenhead, by the Rev E. Downing Pollock vicar, Archibald Gordon Gullan M D., M R.C.P Lond F.R.C.S Eng 37 Rodney street Liverpool, second son of the late Archibald Black Gullan of Swansea, to Agnes third daughter of Ambrose E Goodwin of Oxton

DEATHS

BUTT —On August 28th at Malakand, Frontier Provinces India, George Berkeley Butt I.M.S aged 24

COCKELL.—On Sept. 18th, at Dalston-lane Hackney Frederick Edgar Cockell M R C.S., L.M. aged 72 years

BLACKER.—On Sept. 17th at 16, West Halkin-street, Belgrave-square, S W, Arthur Barry Blacker M D son of the late Rev Maxwell Blacker aged 40 years

N.B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents

MEDICINE-MONEY ON LOAN

THE Wandsworth guardians appear to have inaugurated a form of medical charity which is so far as we are aware, distinctly novel Also it appears to be judicious. They have started a system by which "temporarily necessitous persons may borrow certain sums to secure medicinal necessaries." According to the conditions of the loan it must be repaid by instalments ranging from 1s to half-a-crown weekly Each case is to be dealt with by a combination of the various relief committees Presumably the opinion of a medical officer will be obtained in each case as to the nature and desirability of the "medicinal necessaries." No doubt among the poorer classes in many districts of London the difficulty of paying the druggist weighs more heavily than that of paying the medical man. It is to be hoped that extra efforts to meet the demands of one will not be accompanied by neglect of the other whose deserts are greater though his opportunity for insisting on them is less.

OCULAR SPECTRA.

To the Editors of THE LANCET

SIRS,—Will some of your readers be kind enough to explain the exact cause of the following symptoms? A few weeks ago I had been reading fine print for several hours when quite suddenly the letters appeared indistinct and only parts of them could be seen This condition became so bad I had to stop reading and on looking up saw only parts of the objects around me. There was a circle of a lightish colour dancing before my eyes most of the time. These symptoms lasted about half an hour and when they gradually disappeared I had a head ache which lasted all the evening Twenty years ago when a boy in my teens, I used to have these same symptoms regularly every few weeks but have not had any of them until the attack a few weeks ago. Twelve years ago I had my eyes examined by an ophthalmic surgeon and since then wear appropriate spectacles for myopia. I may state that when looking up at the sky or at white paper I always see "hairs" or black specks Ever since I can remember I have seen a greyish white coloured ball moving in front of my eyes when walking rapidly or exercising in the early morning If I walk rapidly in the morning and look at print parts of the letters are only seen, but this condition only lasts a few seconds. An explanation with treatment will much oblige.

I am Sirs yours faithfully

CLYMONT

Sept. 15th 1902.

FACT OR COINCIDENCE?

To the Editors of THE LANCET

SIRS,—Is it merely a coincidence that the cases of appendix trouble which have passed under my limited observation have been associated with a more or less prominent pomum Adami and is there any parallel to such experience in the observation of others? If I had to advise as to the removal of the appendix as a precautionary measure and merely on my own observations, I should go so far as to say that unusual prominence of the thyroid cartilage would induce me to recommend it. But of course, I know too well the fallacy of limited observations.

I am Sirs, yours faithfully

GEORGE H R DABBS M D Aberd

Shanklin, Isle of Wight Sept. 24th 1902.

MEDICAL ETIQUETTE.

To the Editors of THE LANCET

SIRS —I should like to have your opinion on *the following case of* "want of medical etiquette. I was attending a patient the wife of A's coachman I visited three times and the patient was going on satisfactorily On my fourth visit I was told that A had sent his own medical attendant to see the case that day (four days ago) I have had no communication from A or from his medical attendant. Was the conduct of A's medical attendant professional and gentlemanly towards a fellow practitioner?—I am Sirs, yours faithfully

DISGUSTED

Sept 24th 1902.

* * Either A or his medical attendant or both should certainly have communicated with our correspondent —ED L.

ALABONE AGAIN!

To the Editors of THE LANCET

SIRS —Will you permit me to encroach upon your valuable time to ask your advice in the following matter? My wife is suffering from consumption and having seen in the household weekly *Home Chat* an article on Dr Alabone and his cure which has excited her interest we inquired the cost of his treatment We are informed however that in addition to heavy fees an essential part of the treatment is some special inhalation apparatus which costs between £50 and £70 In view of the costliness of the cure we are anxious to know something more about the man and his system before going to such expense Being so far away there are many difficulties in our way and it has been suggested to us that you might do us the great favour to give us the great benefit of your valued advice in a matter of such vital importance to us Are Alabone and his system worthy of confidence? Is his system the best for the cure of consumption? Trusting you will be so kind as to inform me upon these points &c., for which great favour please accept our sincere and heartfelt thanks

I am Sirs yours faithfully,

Sept 17th 1902 J S

*** Alabone is a quack and we advise our correspondent to have nothing to do with him He should consult a trustworthy medical man either of his own nationality or some foreign practitioner in the town where he lives —Ed L

THE CASE OF DR RAINSBURY

To the Editors of The Lancet

Sirs —Referring to the appeal which you kindly permitted me to make through the medium of The Lancet I beg to inclose a list of the subscribers to the fund Dr Rainsbury and the Council of the Midland Medical Union desire me to express their thanks for the generous response which has been made to the appeal The amount of the judgment and costs is £182 6*s* 2*d*. The donations already received amount to £55 12*s* 3*d* It is hoped that further contributions will be received towards the balance of £126 13*s* 11*d* Will you kindly insert the list of subscribers in the next issue of The Lancet?

I am Sirs, yours faithfully

George S O'Rorke,
Secretary Midland Medical Union.

FICTITIOUS FAME

A remarkable paragraph anent bone-setters their 'triumphs and the case of a well known London actor has recently attracted our attention It is an instance of the manner in which our friends of the lay press only too often do a harm which they are far from intending and spread a reputation which they would be sorry to have to defend There seems to be some subtle fascination about the very word bone-setter and if in addition, a success on the part of an unqualified practitioner can be placed against a failure on that of the real medical man, then the triumph of a journalistic paragraph is ensured In the present instance we are gravely assured that 'specialists averred that the patient had not only a sprain but an American disease of the foot induced by wearing American boots and ordered complete rest for some weeks Upon this prospect of gloom and inactivity enters the leading bone-setter. Magic manipulations and an immediate cure, of course, result We should be interested to hear more about the American disease of the foot" Probably, too, a knowledge of the names of the 'specialists and of the "leading bone-setter" would enable a shrewd guess to be made into the truth underlying the paragraphist's sensational little story

FOREIGN BODIES IN THE LEGS

We cull the following flower from our contemporary the *Westminster Gazette* of Sept 22nd Our contemporary's diagnosis is we should say, one of the many examples of a true word spoken in jest:—

> Railway travelling, as everyone knows is always attended by more or less risk to life and limb The injury received on this account, however and mentioned in the current number of the *Army and Navy Gazette* is surely unique:
>
> An AGED GENTLEMAN (widower, no children) WILL BE REQUIRING soon an experienced Pensioned ARMY or NAVY HOSPITAL VALET His health is perfectly good but he has been severely injured by the upsetting of an express train in his legs He wishes help when he gets out of his bath, and dresses and also in undressing at night. Any applicant must be a member of the Church of England, and state whether married or single.—Apply &c
>
> Considering that an express train has been "upset in them it is remarkable that the advertiser has any legs left at all Clearly a case of locomotor ataxy

CYCLING DURING PREGNANCY

To the Editors of The Lancet

Sirs,—I shall be glad if any of yours readers will give me their experience as regards cycling for women who are pregnant. I have been in the habit of advising cycling so long as no undue discomfort is caused, when of course it is discontinued I have a patient now between three and four months pregnant and she is anxious not to give up cycling as it causes her no inconvenience to ride, say, from 10 to 15 miles Many of her friends say she ought not to cycle

I am, Sirs, yours faithfully,

Sept 23rd, 1902 Regimen

DETAILED MEDICAL ACCOUNTS

To the Editors of The Lancet

Sirs,—I am afraid I cannot agree with your correspondent in The Lancet of Sept. 20th, p 844, when he says that it is the duty of every medical practitioner to render a detailed account when requested; it is all a matter of opinion Already our profession in many parts of this country is rapidly being degraded into a mere trade The difficulty comes in of course when a detailed account is demanded that unless one is prepared to render it redress in the county-court is out of the question, supposing the account to be disputed. However, in my humble opinion patients who are worth having are not the sort who demand details, and it is better to let the others go keep one's self respect, and try to uphold a high standard for the profession There can be no objection to an offer to inspect the ledger at the surgery, as mentioned in "Whitaker," but honourable people know pretty well how much medical attendance they have had and are willing to pay for it.

I am, Sirs, yours faithfully,

Edward Jones, M R C S Eng

St. Columb, Cornwall, Sept 22nd, 1902.

THE REINTERMENT OF THE BODIES OF THOSE HANGED AT NEWGATE

To the Editors of The Lancet

Sirs —A statement has appeared that it is proposed to reinter in Bow cemetery the remains of those executed at Newgate Is it possible, in the interest of science, before the reinterment, for the skulls to be properly examined?

I am, Sirs, yours faithfully,

Leyton E, Sept 24th, 1902. Robert D Sparks

TO MEDICAL FREEMASONS

The executors of the late Lieutenant Colonel S J Flood, R A.M.C. (Mr Richard F Flood of Bundoran and Mr Arthur Tuffield of 5 Brunswick place, Cambridge) earnestly appeal to all medical Freemasons and especially to those connected with the Royal Army Medical Corps, to give their votes to Samuel Basil Flood, youngest son of the above-mentioned Lieutenant-Colonel Flood a nomination having been granted in his favour for election to the Royal Masonic Institution for Boys voting for which takes place on Oct. 10th The late Lieutenant-Colonel Flood had seen much active service including service on the West Coast of Africa He was a most ardent Freemason having been connected with many lodges in this country and in India. He died at the early age of 42 years leaving four young children very inadequately provided for Votes will be gratefully received by Mr Arthur Tuffield at the address given above

◆

E. R S L. would be glad to know the experience of any fellow practitioner who has any knowledge of 'Turvey Treatment of the Tacquaru Company Amberley House, Norfolk street, Strand

Inquirer.—Our correspondent should consult his usual medical attendant who will be both willing and able to give the required information

Mr C Parr.—The laws referring to the practice of dentistry will be found in the Dentists Act, 1878.

During the week marked copies of the following newspapers have been received.—*Windsor and Eton Express Guy's Hospital Gazette, Surrey Advertiser Ayr Observer Grantham Journal, Western Morning News, Hertfordshire Mercury Herts Advertiser Malvern Advertiser Beverley Recorder Nottinghamshire Free Press Newbury Weekly News, Rochester and Chatham Journal and Mid Kent Advertiser Wakefield Express Isle of Man Examiner Fraserburgh Advertiser St. Pancras Gazette, Freeman's Journal, &c.*

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* TO THE EDITORS, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub-Editor

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed To the Manager*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C. are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr CHARLES GOOD THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues and Agents are authorised to collect and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied. Address:—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND
